A thesis submitted to the Nanyang Technological University in partial fulfillment of the requirement for the degree of Doctor of Philosophy

2009
ACKNOWLEDGEMENTS

Firstly, I would like to express my utmost gratitude to my supervisor, Professor Loh Teck Peng for his continual guidance and advice throughout my Ph.D studies. I would also like to extend this gratitude to the past and present group members who have gone through the difficult times with me.

Special appreciation is conveyed to Dr. Chan Kok Ping, Dr. Cheng Hin Soon, Dr. Lu Jun, and Dr. Zhao Yujun for their invaluable discussions and sharing of knowledge.

I would also like to thank the supporting staff in the Division of Chemistry and Chemical Biology, namely Ms. Chen Xiaoping and Ms. Hum Wei Mei for administrative works on graduate student affairs; Ms. Koo Yien Teng and Ms. Woo Lay Khoon for administrative works in the laboratory; Ms. Seow Aihua in the teaching laboratory; Ms. Goh Ee Ling in the NMR laboratory; Mr. Leonard Chay and Madam Zhu Wenwei in the MS laboratory; Prof. Mok Kum Fun and Dr. Li Yong Xin in the X-ray crystallography laboratory.

I would like to express my greatest appreciation to Nanyang Technological University for the award of scholarship and other financial support.

Finally and most importantly, I would like to thank my parents for their continual support and encouragement over the past years.

Appendix 197
SUMMARY

Prins cyclization is now one of the most versatile methods for the synthesis of 2,6-cis-disubstituted tetrahydropyrans from homoallylic alcohols and aldehydes after its rapid methodology development in the past decades. A brief introductory description towards the major aspects of the Prins cyclization is presented in chapter 1, including the prevailing strategies of substrate design, suppression of the racemization of homoallylic alcohols, utilization of the trapping nucleophiles, and Prins cascade reactions.

It still remains a challenge to devise a novel trans Prins cyclization from readily prepared substrates for thermodynamic reasons. In Chapter 2, two strategies were employed to attempt to develop a novel trans Prins cyclization via exploitation of steric and electronic effects. The first strategy utilizing the steric effect (based on \( A \) value) failed to form 2,6-trans-THP rings. However, the second strategy using the electronic effect (static electronic interaction between the lone pair on carbonyl oxygen atom and partially positively charged carbonyl carbon, as depicted in the oxocarbenium intermediate) or neighboring participation effect succeeded in providing us with a novel and efficient trans Prins cyclization in good chemical yields and with good diastereoselectivity.

With properly tailored starting substrates, Prins cascade reactions are effective
in generating novel complex structures with multiple bonds and stereogenic centers formed in a one-pot manner through a combination of the Prins cyclization with other reactions. In Chapter 3 & 4, a convergent and stereoselective Friedel-Crafts-Prins cascade condensation reaction was devised to construct polycyclic THP/DHP rings or furans from propargylic and allylic epoxides. Upon treatment with Lewis acids, cyclic homopropargylic and homoallylic alcohols were formed diastereoselectively via Friedel-Crafts cyclization. For \textit{trans} propargylic epoxide and allylic epoxides, subsequent Prins cyclization afforded the desired polycyclic THP/DHP rings in an efficient and diastereoselective manner. However, complicated situation was encountered when \textit{cis} propargylic epoxide was subjected to the cascade reaction conditions. Polycyclic furans rather than the polycyclic pyrans were obtained in satisfactory yields, and a novel [3+3] annulation reaction of substituted furans was also disclosed in this study.
In Chapter 5, a novel cis Prins cyclization reaction of TMS-substituted allenic alcohols with aldehydes was developed through suppression of undesirable oxonia-Cope rearrangement by tuning the reaction temperature and Lewis acidity. For Me-substituted allenic alcohols, however, it is necessary to incorporate a carbonyl function adjacent to the hydroxyallenyl moiety to suppress the oxonia-Cope rearrangement, and the target DHP rings could only be obtained in moderate yields and with moderate cis/trans stereoselectivities. By far, the application of this methodology to the synthesis of (+)-Sambutoxin was unsuccessful due to the low reactivity of the starting pyridinone aldehyde.

CHAPTER 1

*Prins Cyclization in Modern Organic Synthesis*
1.1 **NATURAL PRODUCTS WITH TETRAHYDROPYRAN AND DIHYDROPYRAN BACKBONES**

Tetrahydropyran (THP) and dihydropyran (DHP) rings constitute the fundamental structural features in numerous natural products. Over the past few decades, there has been a continuous stream of novel natural products with THP/DHP ring backbones isolated from marine sponges and microorganisms. Some examples are illustrated in Figure 1.1. These naturally occurring compounds usually exhibit interesting and important biological activities, such as the antibiotic, antibacterial, antifungal and cytotoxic activities. These properties make these natural products interesting synthetic targets for the organic synthetic community, and also serve as attractive drug candidates for pharmaceutical purposes.

With the justifications evidenced by both academic importance and potential therapeutic values, synthetic interests and efforts remained continually strong towards the development of novel methods for the efficient synthesis of these natural products with THP/DHP rings. Many elegant methodologies have been devised in the past decade for the stereoselective synthesis of functionalized THP/DHP rings in either racemic or enantioenriched manner. These methods include radical cyclization.

---

hetero-Diels-Aldar cycloaddition,\textsuperscript{7} hydroxyl-epoxide cyclization,\textsuperscript{8} oxy-Michael addition,\textsuperscript{9} dioxanone Claisen rearrangement,\textsuperscript{10} Petasis-Ferrier rearrangement,\textsuperscript{11} oxidative carbon-hydrogen bond activation,\textsuperscript{12} Maitland-Japp reaction\textsuperscript{13} and ring closing metathesis\textsuperscript{14} and so on.

Besides all these methods mentioned above, Prins cyclization emerged as one of the most versatile and powerful tools for the diastereoselective synthesis of THP/DHP backbones after the rapid advancement accompanied by various novel methodology studies in the past decades. In the following section, a brief introduction to the Prins cyclization will be presented, focusing on novel methodology development and synthetic applications of towards the total synthesis of natural products.

PRINS CYCLIZATION IN MODERN ORGANIC SYNTHESIS

Figure 1.1 Natural products containing tetrahydropyran (THP) and dihydropyran (DHP) backbones.

- (+)-Centrolobine: Isolated from the heartwood of Centrolobium robustum and from the stem of Brosimum potabile. Exhibit antimicrobial activity and anti-leishmanial effects.

- (+)-Sambutoxin: Isolated from wheat cultures of Fusarium sambucinum PZF-4. Exhibit antibiotic, antiinsectidal, antifungal, and antitumor activity.

- Bryostatin 1: Exhibit anticancer properties and has been shown to synergize the effects of other antineoplastic agents, promote apoptosis, reverse multidrug resistance, and stimulate the immune system.

- Phorboxazole A: Macrolone with anti-tumour activity

- Leucascandrolide A: Isolated from the thecalcareous sponge Leucascandra cavesolata. Exhibit high cytotoxicity against human KB tumor cell lines and potent antifungal activity.

- Methyl Sarcophytute: Isolated from Sarcophyton glaucum. Exhibit cytotoxicity.

- (+)-SCH 351448, a novel activator of low-density lipoprotein receptor promoter with an IC50 of 25 µM.
1.2 General Discussion on Prins Cyclization

1.2.1 Prins Reaction

From a historical perspective, the concept of Prins cyclization comes from the Prins reaction. Since the pioneering systematic studies by H. J. Prins, the Prins reaction has come to become an important carbon-carbon bond formation tool via the condensation of alkenes with aldehydes catalyzed by mineral acids. It is well-established that from a mechanistic point of view, the Prins reaction is of cationic nature proceeding in a step-wise manner. The resultant carbocation formed in the Prins reaction can undergo elimination, nucleophilic trapping or acetalization with excess aldehydes to form different products. The final outcome of this reaction depends on the substrates and reaction conditions, and various condensation products could be obtained, including 1,3-diols, 1,3-dioxanes and unsaturated alcohols (Scheme 1.1). Extensive studies revealed its uncontrollable nature in terms of the chemo- and regio-selectivity, which severely limited its applications in organic synthesis.

![Scheme 1.1 Prins reaction of olefins with aldehydes.](attachment:image)

1.2.2 Prins Cyclization

In contrast to the uncontrollable Prins reaction, its advanced version, the Prins cyclization, emerges as one highly valuable, efficient, versatile and superior tool for diastereoselective synthesis of tetrahydropyran and dihydropyran rings as a result of intensive research and rapid advancement in the past decades.

One general strategy for carrying out the Prins cyclization is to append the allylic moiety of a molecule (e.g. a homoallylic alcohol) onto an oxocarbenium cation, which is generated in situ from an aldehyde in the presence of a Lewis or Brønsted acid, followed by trapping with a nucleophile to yield 2,4,6-trisubstituted tetrahydropyran (Scheme 1.2).

\[
\begin{align*}
R_1 &\xrightarrow{\text{L.A.}} R_1\xrightarrow{\text{Nu}} \text{2,4,6-trisubstituted tetrahydropyran} \\
R_1\xrightarrow{\text{L.A.}} R_1 + \text{Nu} &\xrightarrow{\text{2,4,6-trisubstituted tetrahydropyran}} \\
\end{align*}
\]

Scheme 1.2 Prins cyclization of homoallylic alcohols with aldehydes.

Li\textsuperscript{17} reported a \textit{InCl}_3-mediated Prins cyclization of homoallylic alcohols with aldehydes, where a stoichiometric amount of \textit{InCl}_3 was used as both the promoter and the halogen counterion source to afford \textit{meso}-4-chloro-THP rings (Scheme 1.3). Despite of the good yields and stereoselectivity, only the \textit{meso}-products were obtained, which severely limited its synthetic applications.

\[
\begin{align*}
\text{OH} &\xrightarrow{\text{InCl}_3 (110 \text{ mol}\%)} \text{Cl} \\
\end{align*}
\]

Scheme 1.3 Prins cyclization mediated by stoichiometric \textit{InCl}_3 forming \textit{meso}-THP rings.

For synthetic purposes, our group devised a novel and efficient \textit{In(III)} complex-catalyzed asymmetrical Prins cyclization by using silyl halides as the

counterion source to construct 2,6-cis-disubstitued-4-halo-tetrahydropyran rings in excellent yields and diastereoselectivity (Scheme 1.4). In addition, the synthetic value of this method was elegantly demonstrated in the total synthesis of (-)-Centrolobine. Epimerization originating from a undesirable allyl-transfer process (oxonia-Cope rearrangement) was successfully suppressed with complete retention of chirality of the starting homoallylic alcohol by tuning the Lewis acidity and the reaction temperature (Scheme 1.4). Importantly, this methodology offers an effective solution to the racemization problem frequently encountered in Prins cyclization which is caused by a symmetric oxonia-Cope rearrangement (Scheme 1.5). Still on this topic, Willis proposed a mechanism for the formation of meso-THP side products in his study of BF$_3$·OEt$_2$-mediated Prins cyclization (Scheme 1.5).

![Scheme 1.4 In(III) complex catalyzed Prins cyclization using silyl halides to 2,4,6-trisubstituted THP rings and its application to the total synthesis of (-)-Centrolobine.](image)

Prior to our findings in suppressing epimerization, Rychnovský disclosed an effective method to overcome this problem by using the SnBr$_4$ instead of BF$_3$·OEt$_2$/AcOH to promote the cyclization, where it was rationalized that SnBr$_4$

---

promotes cyclization much faster than BF$_3$·OEt$_2$/AcOH, resulting in the suppression of the competing symmetric oxonia-Cope rearrangement (Scheme 1.5).$^{5b,20}$

![Scheme 1.5](image)

Besides (-)-Centrolobine, the versatility and synthetic value of our asymmetrical catalytic Prins cyclization methodology was further demonstrated as the key strategy in the elegant formal synthesis of (+)-SCH 351448 (Scheme 1.6).$^{21}$ It also featured adoption of several other strategies for the preparation of the major precursors, including aqueous Mukaiyama aldol, Suzuki-Miyaura coupling, and Brown’s allylation/crotylation. The key step in the synthesis of the monomeric unit is successfully achieved through catalytic Prins cyclization in moderate yield without significant racemization.

---

Formation of the oxocarbenium cation is one of the central topics in Prins cyclization. Rychnovsky has reported an elegant THP formation method via the segment-coupling Prins cyclization strategy (Scheme 1.7).\textsuperscript{22} The starting \( \alpha \)-acetoxy ethers could be readily prepared from the corresponding homoallylic alcohols over three steps: coupling to the homoallylic ester; DIBAL-H reduction of the homoallylic ester, and acetate protection of the resulting hemiacetal. Upon treatment with a Lewis

acid, the oxocarbenium cation intermediate is spontaneously generated through the solvolysis of the $\alpha$-acetoxy ether precursor, which then cyclizes to form asymmetrical THP rings in the presence of counterion. The elegance of this strategy was illustrated in the extremely concise construction of the key precursor for phorboxazole synthesis.

\[
\begin{align*}
\text{R}_1\text{OH} & \xrightarrow{\text{R}_2\text{CO}_2\text{H}} \text{R}_1\text{O} \xrightarrow{\text{DIBAL-H}} \text{R}_1\text{OAc} \xrightarrow{\text{MX}_n, \text{Lewis Acids}} \text{THP}
\end{align*}
\]

Scheme 1.7 Rychnovsky’s segment-coupling Prins cyclization strategy for THP ring synthesis.

In addition, allylic 1,3-dioxanes are also ideal precursors to generate the oxocarbenium cation intermediates in the Prins cyclization because the acetal function can be cleaved regioselectively upon treatment with a Lewis acid (Scheme 1.8). Tetrahydropyrans are formed diastereoselectively after cyclization of the allylic moiety onto the oxocarbenium cation intermediates generated \textit{in situ}. This strategy also found its application as the key step in the elegant total synthesis of (-)-Blepharocalyxin D.24

\[\text{R}_1\text{OH} \xrightarrow{\text{Lewis Acids}} \text{AcO} \xrightarrow{\text{BF}_3\text{OEt}_2, \text{AcOH}, 52\%} \text{THP} \]

\[\text{R}_1\text{O} \xrightarrow{\text{AcO}} \text{OAc} \]

\[\text{R}_2\text{CO}_2\text{H} \]

Besides the common counterions, such as halides (Cl\(^-\), Br\(^-\), I\(^-\)),\(^{18}\) F\(^-\),\(^{25}\) OTs\(^-\), OH\(^-\),\(^{26}\) and OAc\(^-\),\(^{19}\) cationic reaction intermediates were also observed to trap nuleophilic solvents during the cyclization, such as arenes via a Friedel-Crafts type alkylation,\(^{23a, 27}\) alkyl nitriles via a Sakurai-Prins-Ritter sequence\(^ {28}\) (Scheme 1.9). Rychnovsky disclosed a sophisticated utilization of the nucleophile for trapping the oxocarbenium cation intermediate in the synthetic studies towards the calyxins.\(^ {29}\)

Scheme 1.9 Trapping of solvents during Prins cyclization for novel THP rings synthesis.

The regioselectivity of the Prins cyclization depends on the structure of the allylic/propargylic fragment and reaction conditions. Normally, Prins cyclization proceeds via two possible pathways: the conventional 6-endo cyclization (pathway I) to THP/DHP rings, and the 5-exo cyclization (pathway II) to THF rings (Scheme 1.10).\(^{30}\) In this area, our group has demonstrated an In(OTf)\(_3\)-catalyzed Prins-type cyclization of homoallylic alcohols with aldehydes to afford tetrahydrofuran rings in good yields and selectivity.\(^{31}\) In addition, for the Prins-type cyclization of propargylic alcohols, the divergent formation of dihydropyran\(^{32}\) and tetrahydrofurans\(^{33}\) had also

been documented with good stereoselectivity and chemical yields, where the regioselectivity was also substrate and reaction conditions dependent.

Under most circumstances, high 2,6-cis-diastereoselectivity is observed for the Prins cyclization. Formation of the chair-like oxocarbenium transition state is thermodynamically favored so as to avoid severe 1,3-diaxial interaction, resulting in predominant generation of the 2,6-cis-THP rings (Scheme 1.11).

Despite these elegant Prins cyclization methods described above, Prins cascade reactions become more and more appealing to synthetic chemists because of the intrinsic advantages and efficiency in forming multiple bonds and stereogenic centers in an one-pot manner through a combination of the Prins cyclization with
other reactions. Our group devised a In(III) complex-catalyzed one-pot Prins cyclization by using allylchlorosilane as the allylating reagent and also the counterion source to afford 2,6-cis-disubstituted tetrahydropyrans in good yields and diastereoselectivity (Scheme 1.12).\textsuperscript{34} The usage of catalytic amount of Lewis acids and the one-pot operation for facile access to THP rings make this methodology valuable and attractive for synthetic purposes.

![One-pot Prins cyclization using allylchlorosilane as allylating agent.](image)

In this respect, Rychnovsky devised an elegant and powerful Mukaiyama Adol-Prins cyclization cascade reaction to form a novel tetrahydropyran ring with concurrent generation of an alcohol function (Scheme 1.13).\textsuperscript{35} Enol ether underwent a Mukaiyama adol condensation with Lewis acid activated aldehydes to form the oxocabeniunm cation intermediate \textit{in situ}, followed with a Prins cyclization of the allylic moiety to afford a THP ring. The utility of this strategy was demonstrated in its concise application in the formal total synthesis of Leucascandrolide A macrolide.

Scheme 1.13 Mukaiyama Adol-Prins cyclization cascade reaction and formal synthesis of Leucascandrolide A.

In addition to the formation of THP rings, Prins cascade reactions are also capable of generating novel complex structures by exploiting properly tailored starting substrates. For instance, bicyclic annulation products (7-(silyloxy)-2-oxabicyclo[2.2.1] heptanes) could be constructed in one operation via an intramolecular double Prins cyclization cascade reaction triggered by Lewis acid from α-hydroxy aldehydes with an electron-rich double bond (Scheme 1.14). More importantly, the chemical yields were further improved to 84-92% by carrying out this cascade reaction from the corresponding diols through a Swern oxidation and the subsequent activation sequence.

---

Interestingly, intermolecular double Prins cyclization cascade reaction has also been documented to afford novel complex oxygenated heterocycles. In a recent account, Cho reported an efficient and facile method to make 1,6-dioxecanes via an intermolecular double Prins-type cyclization of allenylsilanes with aromatic aldehydes (Scheme 1.15). This cascade sequence offers an effective approach to make entropically disfavored medium-sized oxygenated heterocycles via Prins cyclizations.

Scheme 1.14 Intramolecular double Prins cyclization to novel bicyclic heptane rings.

Scheme 1.15 Intermolecular double Prins cyclization to novel oxygenated heterocycles.

1.3 DEVELOPMENT OF NOVEL PRINS CYCLIZATION REACTIONS

After a general discussion of some of the available methods used to construct THP rings, it is notable that some methods are confined to small molecule synthesis and the construction of small fragments in a stepwise manner to build up the structural cores in the application to natural product synthesis. Importantly, it still remains a challenge for synthetic chemists to devise a novel Prins cyclization to access 2,6-*trans*-substituted THP/DHP rings from readily prepared substrates.

Although a variety of substrates and strategies have been devised for construction of 2,6-*cis*-substituted THP/DHP rings *via* Prins cyclization, there exists an undying demand for novel, milder, straightforward and convergent methods to make THP/DHP rings, especially in an efficient cascade reaction manner. Sophisticated design of substrates and careful screening of reaction conditions are essential for the discovery of novel Prins cascade reactions.
CHAPTER 2

Development of Novel \textit{trans} Prins Cyclization Reaction
2.1 INTRODUCTION

Although the 2,6-cis-tetrahydropyran (THP) motif is commonly encountered in various biologically active marine natural products, however, there are also a large number of natural products containing the 2,6-trans-tetrahydropyran framework (Figure 2.1). These compounds exhibit important biological activities, including anti-tumor, anti-fungal and anti-bacterial properties, which makes them highly valuable screening candidates for discovery of new pharmaceuticals. Thus, strong interest has been long directed towards the development of novel methods to synthesize these 2,6-trans-tetrahydropyrans.

Figure 2.1 Natural products with 2,6-trans-tetrahydropyran frameworks.
2.2 General Methods for Construction of 2,6-trans Tetrahydropyrans

2.2.1 Substrate-Controlled Stereospecific Cyclization

Several methods have been developed to make 2,6-trans-disubstituted tetrahydropyran rings. Ho reported a general and stereospecific method for the preparation of 2,6-trans-disubstituted tetrahydropyrans with excellent diastereoselectivity (Scheme 2.1).¹ The linear substrate was prepared over several chemical transformations with the complete carbon skeleton and functionalities assembled. The 2,6-trans-disubstituted tetrahydropyran was smoothly formed via intramolecular SN2 type displacement under basic condition or via an alternative hydroxyl addition to epoxy functionality when treated with acetic acid.

![Scheme 2.1 Stereospicific SN2 type cyclization to 2,6-trans-tetrahydropyran.](image)

In addition to the hydroxy-displacement or hydroxy-epoxide cyclization strategy, intramolecular oxy-Michael type cyclization of 7-hydroxy-2-enimide upon treatment with base offers an alternative approach to generate the trans-isomer with excellent diastereoselectivity as demonstrated by Schneider (Scheme 2.2).² It was revealed that the stereoselectivity of the cyclization is substrate-dependent and the chiral auxiliary only plays a supporting role. Interestingly, reversal of selectivity

---

could be achieved by using hydroxyenoate instead of the enimide, and molecular orbital interaction between the lone pair of the oxygen and the anti-bonding $\pi^*$ orbital of the conjugate double bond was proposed to account for this stereoselectivity.

Rein also reported a base mediated oxy-Michael type cyclization of (E)-hydroxy-acrylate to afford the 2,6-trans-tetrahydropyrans with excellent diastereoselectivity (Scheme 2.3). The acrylate group is forced to reside on an axial position in order to form the favorable chair-like transition state, which simultaneously maximizes overall chelating with K$^+$ ion.

2.2.2 Anomeric Oxygen to Carbon Rearrangement

Ley$^4$ reported an elegant method through anomeric oxygen to carbon rearrangement to prepare 2,6-trans-tetrahydropyrans, by treating 2,6-cis-tetrahydropyrans enol ether with Lewis acid at low temperature, in satisfactory yields.

---

DEVELOPMENT OF NOVEL TRANS PRINS CYCLIZATION REACTION

and excellent diastereoselectivity (Scheme 2.4). Catalytic amount of TMSOTf activates the leaving group leading to the formation of oxonium ion and silyl enol ether in situ. These components recombine kinetically to afford the trans-pyranyl-ketone products.

![Scheme 2.4 Anomeric oxygen to carbon rearrangement of 2,6-cis-tetrahydropyranyl enol ether.](image)

2.2.3 Nucleophilic Addition

It is well established that carbohydrate derivatives undergo nucleophilic displacement easily with preferential formation of the axial isomer in the presence of a Lewis acid and a soft nucleophile.\(^5\) Recently, Branbander\(^6\) demonstrated a facile introduction of an axial nitrile onto pyranyl motif by ZnI\(_2\)-mediated acetate displacement with trimethyl cyanide in the synthesis of psymberin analogues (Scheme 2.5).\(^7\)

---

DEVELOPMENT OF NOVEL TRANS PRINS CYCLIZATION REACTION

Scheme 2.5 Functionalization of pyranyl acetate in synthesis of pesympederin.

In addition, Williams\(^8\) disclosed an elegant Mukaiyama-aldol transformation of pyranyl acetate with enol ether in high yield and excellent diastereoselectivity in a second generation formal synthesis of leucascandrolide A.\(^9\)

Scheme 2.6 Mukaiyama-aldol process of pyranyl acetate in synthesis of leucascandrolide A.

\[ \text{Scheme 2.6 Mukaiyama-aldol process of pyranyl acetate in synthesis of leucascandrolide A.} \]

2.2.4 Diastereoselective Reductive Opening of Bicyclic Ketal

DeShong recently developed a novel reductive opening of bicyclic ketal to form 2,6-trans-pyran derivatives in a highly regio- and stereoselective manner.\(^{10}\) It was proposed that a pyran-oxonium ion is formed when the aluminum reagent coordinates to the O(3)-ketal oxygen under nonpolar conditions in the DIBALH

---

reduction. Hydride attack occurs preferentially from the same direction as a result of the rapid intramolecular capture of the oxonium ion, leading to the trans stereoselectivity (Scheme 2.7). The power of this method was elegantly demonstrated in the enantioselective total synthesis of (+)-Leucascandrolide A macrolactone. The bicyclic ketal could be derived from a Homer-Wadsworth-Emmons reaction between the corresponding aldehydes and ketone phosphonate, which makes this strategy highly attractive from a synthetic point of view.

Scheme 2.7 Diastereoselective reductive opening of bicyclic ketal.

2.2.5 Etherization and Ring Closing Metathesis

Rhodium(I)-catalyzed etherification of an allylic carbonate with optically pure homoallylic alcohols, followed by ring-closing metathesis proceeded with excellent diastereoselectivity to afford 2,6-cis- and 2,6-trans-dihydropyrans in high yields (Scheme 2.8).  

2.3  **PRINS CYCLIZATION TO 2,6-TRANS-TETRAHYDROPYRAN**

2.3.1  **Substrate-Controlled 2,6-trans-Prins Cyclization: Steric Effect.**

In the synthetic study of Okadaic acid, Markó\textsuperscript{12} reported a steric compression strategy to construct 2,6-trans dihydropyran in an effective manner. When anti-silyl ether was subjected to the intramolecular Silyl-Modified Sakurai (ISMS) reaction, it could react via two possible transition states (Scheme 2.9). Nevertheless, severe 1,3-diaxial interaction between the SiMe\textsubscript{3} substituent and the ethyl group should strongly disfavor formation of the 2,6-cis-isomer. Thus, only 2,6-trans-dihydropyran was formed as the single diastereoisomer in satisfactory yield.

However, only the 2,6-cis-isomers could be obtained in those cases without the essential substituent that is trans to the OTMS group both in ISMS reaction\textsuperscript{12} and in Prins-type cyclizations.\textsuperscript{13}

Later, Panek\textsuperscript{14} reported a more sophisticated stereoselective [4+2] annulation of chiral anti-hydroxycrotylsilane to afford 2,6-trans-pyran ring (Scheme 2.10). A pseudo-axial orientation for the silyl group has been proposed for effective $\sigma$-$\pi$ overlap in a boat-like transition state. This conformation determines the \textit{trans} cyclization stereo-outcome, which is rationalized through an \textit{anti-}S_{E}' mode of addition. From the viewpoint of both steric and electronic considerations, the bulky silyl group will be placed in an \textit{anti} orientation to the neighboring ester group in the oxocarbenium intermediate, resulting in the desired \textit{trans}-isomer upon cyclization. The efficiency of this strategy has been elegantly demonstrated in the synthetic studies of many natural products, such as Leucascandrolide A,\textsuperscript{14b} Callipeltoside A,\textsuperscript{14c} Kendomycin,\textsuperscript{14d} and Bistramide A.\textsuperscript{14c, 15}

![Scheme 2.10](image-url)

Scheme 2.10 \textit{trans}-Prins cyclization of chiral \textit{anti}-hydroxycrotylsilane.

Speckman devised an intramolecular Prins cyclization of \((E)\)-vinylsilanes to form 2,6-\textit{trans}-dihydropyran rings.\textsuperscript{16} The \textit{trans} selectivity was rationalized as originating from the most preferred cyclization conformation featuring an axial silyl function, which comes from reorganization of the reaction intermediates via a cationic oxonia-Cope rearrangement and a subsequent chair-chair interconversion (Scheme 2.11).\textsuperscript{16} In the case of the \((Z)\)-vinylsilanes, only \textit{cis} cyclization was observed, where the oxocarbenium cation has an equatorial ester substituent with the TMS function axially oriented because of the \((Z)\)-double bond geometry. Yu\textsuperscript{17} also disclosed a similar strategy to construct 2,6-\textit{trans}-dihydropyrans in good yields and stereoselectivity using a titanium-based catalyst.

\begin{Scheme}
\begin{center}
\includegraphics[width=0.8\textwidth]{Scheme2.11.png}
\end{center}
\end{Scheme}

\textit{Scheme 2.11} Intramolecular Prins type cyclization of vinyl silane.

2.3.2 Substrate-Controlled 2,6-trans-Prins Cyclization: Electronic Effect.

In the synthetic study of (-)-Apicularen A,\textsuperscript{18} Panek observed that a *syn*-organosilane with methyl ether as the terminal substituent can be used to afford 2,6-*trans*-dihydropyran in excellent diastereoselectivity.\textsuperscript{19} A twist boat-like transition state was proposed to account for this stereochemical outcome. The electrostatic attraction between the nonbonding lone pair of electrons on the methoxy group and the positively-charged oxocarbenium cation, which resides on the carbon atom, can stabilize the twist boat conformer and accelerates the annulation (Scheme 2.12).

![Scheme 2.12 trans-Prins Cyclization of syn-methyl ether crotyl silane.](image)

Chan,\textsuperscript{20} a senior member in our group, also devised a *trans* cyclization channel which utilizes the lone pair directing effects for stabilizing the oxocarbenium cation in Prins cyclization. By incorporating ester functionality onto the homoallylic alcohol, spatial electrostatic interaction overcame 1,3-diaxial steric repulsion in the chair-like transition state \textbf{I}, thus resulting in the formation of the *trans*-isomer (Scheme 2.13) in moderate selectivity and yields. However, the cyclization also proceeded quite well

when the electron rich moiety (isopropyl ester) adopts the equatorial position (transition state II), thus lowering the overall trans selectivity.

Scheme 2.13 Competing steric and electronic effects in substrate-controlled Prins cyclization.

During the total synthesis of scytophycin C, Roush devised a strategy to access 2,6-trans-dihydropyrans via Prins cyclization of β-hydroxyallylsilane with aldehydes (Scheme 2.14).\textsuperscript{21} The trans selectivity was expected to originate from a chair transition state with axial R\textsubscript{1} and TMS, where the axially oriented TMS is preferred for stereoelectronic reasons when forming the carbocationic structure at the β–position.\textsuperscript{22} However, 2,6-cis-cyclization was found to predominate. It was finally revealed that all the reaction processes involved in this study proceeded via a boat-like conformation with high stereochemical retention after a careful examination of the absolute C-O stereochemistry.

2.4  **Development of Novel trans Prins Cyclization Reaction**

2.3.1 From Steric Effect

It is established after the general discussions described above that both steric and electronic effects could be utilized to devise novel trans Prins cyclization. Here, we conceived a strategy by utilizing the A value\(^\text{23}\) to develop a novel trans Prins cyclization reaction, where syn vinyl bromohydrin was selected as the candidate substrate to form 2,6-trans-THP rings (Scheme 2.15). The trans selectivity is based on the hypothesis that \(R_1\) should be forced to assume an axial position by the bulky bromo-substituent, which prefers to occupy an equatorial position in order to avoid strong 1,3-diaxial repulsive interaction. Based on this assumption, if the cyclization does proceed through transition state I, 2,6-trans-THP rings will be obtained with all bromo-substituents residing at equatorial positions.

![Scheme 2.15 Hypothesized trans Prins cyclization of syn vinyl bromohydrin based on A value.](image)

A mixture of 1 (\(\text{syn} : \text{anti} = 3 : 1\)) was subjected to the standard Prins cyclization condition\(^\text{24}\) developed in our group, and the two Prins cyclized products 2 and 3 were obtained in 47% and 16% yields respectively (Scheme 2.16). The relative stereochemistry was determined by NOESY experiments. For both \(\text{syn}\) and \(\text{anti}\)

---

\(^{23}\) A value denotes the 1,3-diaxial interaction on six membered rings, see: Corey, E. J.; Feiner, N. F. *J. Org. Chem.* 1980, 45, 765.

bromohydrins, Prins cyclization reaction may proceed via two possible transition states I and II, however, transition state I is actually disfavored because of the severe 1,3-diaxial repulsion between the alkyl chain and the aldehydic proton, as depicted below. In contrast to our initial envision, bromine substituent was found to be capable to reside on axial position because of its relative small A value, which makes transition state II favorable during the cyclization of the syn bromohydrin. For this reason, only 2,6-cis-THPs were formed in this case. Thus, our strategy exploiting A value failed to form the desired 2,6-trans-THP rings from syn vinyl bromohydrins.

Scheme 2.16 Prins cyclization of syn and anti bromohydrin with aldehydes.

Although we failed to obtain the desired 2,6-trans-THP rings, we envisage that 2,6-cis-dibromo-THP rings could serve as potentially important precursors to form other THP-containing compounds via further elaborations, such as debromination to form a double bond selectively. Interestingly, Blepharocalyxins D & E are believed to be synthesized from a precursor with a double bond on the pyran ring from a biogenetic point of view.25

Because of the difficulties in preparing and purifying 1, we devised an alternative approach to make the 2,6-\textit{cis}-dibromo-tetrasubstituted THP rings by using (Z) and (E)-\textit{γ}-brominated homoallylic alcohols in the presence of indium-based Lewis acids, which will offer an opportunity to further confirm the stereochemistry involved in the \textit{cis} Prins cyclization of \textit{syn} vinyl bromohydrins with aldehydes (Scheme 2.17).\textsuperscript{26, 27}

\begin{equation}
\begin{array}{c}
\text{OH} \quad R_1 \quad \text{CHO} \quad X \quad \text{Br} \\
\text{Br} \quad \text{OH} \quad R_2
\end{array}
\end{equation}

Scheme 2.17 Prins cyclization of \textit{γ}-brominated homoallylic alcohol with aldehydes.

\textit{γ}-Brominated homoallylic alcohol (Z)-4 and cyclohexanecarboxaldehyde were selected for the optimization of reaction conditions (Scheme 2.18). Indium-based Lewis acids, such as InCl\textsubscript{3}, In(OTf)\textsubscript{3} and InBr\textsubscript{3} were employed to mediate the Prins cyclization at 0 °C in CH\textsubscript{2}Cl\textsubscript{2}. No Prins product was formed when InCl\textsubscript{3} was utilized to promote this cyclization and no desired crossed product could be obtained when using In(OTf)\textsubscript{3}.

\begin{equation}
\begin{array}{c}
\text{OH} \quad R_1 \quad \text{CHO} \quad \text{Br} \\
\text{Br} \quad \text{OH} \quad R_1 \quad \text{Br} \quad \text{Br}
\end{array}
\end{equation}

Scheme 2.18 Prins cyclization of (Z)-4 with cyclohexanecarboxaldehyde.

\textsuperscript{27} (Z)-4 was prepared in 62% yield by using hydrocinnamaldehyde to trap allylic anion generated from allyl bromide in the presence of LDA and zinc bromide.\textsuperscript{26c} (E)-5 was prepared in three steps: (1) propargylation of trialkylsilyl propargyl bromide with hydrocinnamaldehyde mediated with indium and indium bromide (60%),\textsuperscript{26c} (2) DIBAL-H reduction converting the triple bond into the \textit{cis} double bond (64%),\textsuperscript{26d} (3) bromination (90%).\textsuperscript{26c,f}
However, InBr₃ was discovered to be a highly efficient Lewis acid to promote this Prins cyclization and the yields were dependent on the amount of InBr₃ employed (Table 2.1, entries 1, 2 and 3), with the best condition being 1.0 equiv. of InBr₃ with 1.2 equiv. of TMSBr in CH₂Cl₂ at 0 °C to afford 5 in 95% yield as a single isomer (Table 2.1, entry 3). This cyclization proceeded smoothly with high stereoselectivity and introduced four stereogenic centers into the product in one step. 2,4,6-cis-5-trans THP ring 5 was expected to be constructed with an axial bromine substituent at 5 position and all other three substituents occupying equatorial positions. This was confirmed by the X-ray crystal structure of 5 (Figure 2.1).

![Figure 2.1 Crystal structure of 5, showing an axial bromine at 5 position and all equatorial substituents at 2,4,6 positions.](Image)

Using the above optimized reaction conditions (Table 1, entry 3), a variety of aldehydes were selected to construct the 2,6-cis-4,5-dibromo-THP rings with both

---

28 Our initial investigations revealed that TMSBr serves as a bromide source. No reaction occurred when only TMSBr was used as promoter. With stoichiometric amount of InBr₃ as the sole promoter, only trace amount of the product could be observed when (Z)-4 was reacted with cyclohexanecarboxaldehyde; for (E)-11 only 21% yield was obtained.

29 Crystal data for 5 see Appendix.

30 Typical experimental procedures for our Prins cyclization to 2,6-cis-4,5-dibromo-THP rings: to an oven-dried round-bottom flask with a magnetic stirrer was added indium bromide 106.0 mg (0.30 mmol, 1.0 equiv.) and anhydrous dichloromethane 1.5 mL. The mixture was vigorously stirred at 0 °C. (Z)-4 91.8 mg (0.36 mmol, 1.2 equiv.) dissolved in 1 mL anhydrous CH₂Cl₂ was introduced into the suspension, and 5 minutes later bromotrimethylsilane TMSBr 0.05 mL (0.36 mmol, 1.2 equiv.) was added. Cyclohexanecarboxaldehyde 33.7 mg (0.30 mmol, 1.0 equiv.) dissolved in 1 mL anhydrous CH₂Cl₂ was slowly introduced over 10 minutes. The reaction was allowed to proceed at 0 °C for 90 minutes before quenching with saturated sodium bicarbonate solution (5 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane) to afford 5 as a white solid in 95% yield.
(Z)-4 and (E)-11, and moderate to good yields with excellent stereoselectivities were obtained. The results are summarized in Table 2.1 and Table 2.2.

Table 2.1 Prins cyclization of (Z)-4 to 2,6-cis-4,5-dibromo-tetrasubstituted tetrahydropyrans.

Scheme 2.19 Chemical transformations of 2,6-cis-4,5-dibromo-THP rings.
THP products 5 and 12 were selected to perform a series of chemical transformations to explore the synthetic versatilities of our dibromo-THP rings (Scheme 2.19). As expected, 18 was readily obtained with a selective double bond via direct debromination using activated zinc in acetic acid at room temperature, and an unexpected alternative approach was also discovered to create such selective double bond under radical reaction conditions (Table 2.3, entries 3 and 4).

The presence of axial bromine makes 5 more reactive compared to 12 (all bromine equatorial). The double bond of 18 allows further functionalizations, such as epoxidation and hydroxylation. In addition, elimination product 19 was formed when 5 and 12 were treated with potassium tert-butoxide. 5 was again found to be more reactive than 12. Results are summarized in Table 2.3. Vinyl bromide 19 is also a versatile intermediate which can be converted into 2,6-alkyl-3-hydroxy-tetrahydro-pyran-4-one via osmium-catalyzed cis-dihydroxlation or into 2,6-disubstituted-THP ring upon catalytic hydrogenation using Pd/C.

2.4.2 From Electronic Effect

As mentioned above, our group’s trans Prins cyclization utilized the electronic directing effect leading to a moderate trans selectivity. Here, we progress further in our studies towards this topic to achieve a higher trans/cis selectivity by using this electronic directing effect. In our group’s reported method, the moderate trans diastereoselectivity originated from the spatial electrostatic interaction that overcame steric repulsion (1,3-diaxial interaction) in the chair-like transition state I (Scheme 2.13). We wonder whether a higher trans diastereoselectivity could be achieved if we remove the 1,3-diaxial interaction by changing the allyl group to a linear allenyl functionality. Bearing this thinking in mind, we devised another trans cyclization by subjecting allenyl alcohol with carbonyl functionality to Prins cyclization conditions.

By subjecting allenyl alcohol bearing \( \alpha \)-alkoxycarbonyl group \( 20 \) to Prins cyclization conditions (10 mol % In(OTf)\(_3\), 1.2 equiv. of TMSBr, 0 °C, in CH\(_2\)Cl\(_2\)) developed in previous studies), \(^{24a}\) the desired 2,6-trans-disubstituted-4-bromo-3,4-dihydropyrans were formed smoothly in good yields with high trans diastereoselectivity (Scheme 2.20). \(^{35}\)

Scheme 2.20 Prins cyclization of Me-substituted allenyl alcohol bearing \( \alpha \)-alkoxycarbonyl group.

\(^{35}\) This part of work was done in collaboration with a group member, see: Hu, X. H.; Liu, F.; Loh, T. P. Org. Lett. 2009, 11, 1741.
Interestingly, the \textit{trans} diastereoselectivity was further enhanced to a higher level of up to \( > 99:1 \) when TMS substituted allenyl alcohol bearing \( \alpha\)-alkoxycarbonyl group 27 was utilized for this Prins cyclization (Scheme 2.21), where the TMS group strongly prefers to adopt an axial position for stereoelectronic reasons in reactions that develop carbocationic character at the \( \beta \)-position.\textsuperscript{21, 22} Thus, an enhancement of the repulsive effect in transition state IX and X probably further suppressed the formation of the undesired 2,6-\textit{cis} DHP isomers.

Scheme 2.21 Prins cyclization of TMS-substituted allenyl alcohol bearing \( \alpha\)-alkoxycarbonyl group.

The alkoxycarbonyl function adjacent to the allenic alcohol motif played a central role for this 2,6-\textit{trans} diastereoselectivity: firstly, it serves to suppress the undesired oxonia-Cope rearrangement, because the electron-withdrawing alkoxycarbonyl function disfavours the oxonia-Cope rearrangement product in which the alkoxycarbonyl function is directly attached to the oxonium carbon;\textsuperscript{21} secondly, the stereoelectronic interaction between the lone pair on the carbonyl oxygen and the partially positive-charged oxonium carbon directs the alkoxycarbonyl group to adopt an axial orientation, resulting in the 2,6-\textit{trans} diastereoselectivity. Alternatively, the \textit{trans} selectivity originates from the 1,2-neighboring participation effect that leads to the formation of 5-membered transiton states IV, VIII, however, transition states VI, X are less favored due to the intrinsic steric repulsions.
2.5 CONCLUSION

From the point of view of steric effect, our A value strategy failed to provide us with a novel trans Prins cyclization reaction. It is established that the syn vinyl bromohydrins underwent cis Prins cyclization via chair-like transition states affording only 2,6-cis-THP products as evidenced by the crystal structure of 5 (Figure 2.1). To our delight, we have developed an efficient Prins cyclization reaction to construct 2,6-cis-4,5-dibromo-tetrasubstituted THP rings with excellent diastereoselectivity in good yields. Effective control of the stereochemistry of the bromo-substituent at C(5) position was achieved by manipulating the geometric configuration of the γ-brominated homoallylic alcohols. This method offers a stereoselective approach to make dibromo-THP rings via Prins cyclization that results in a cis configuration of bromine atoms. Other approaches to dibromo-THP rings were realized via bromination of dihydropyrans, and only trans addition products were obtained.36 Our dibromo-THP products serve to provide versatile intermediates that allow further functionalization to various substituted pyran-containing compounds.

Our second strategy succeeded in disclosing a novel, highly efficient trans Prins cyclization by utilizing allenyl alcohol bearing α-alkoxycarbonyl group. The high trans diastereoselectivity probably originates from the spatial electrostatic directing effect between the lone pair of electrons on carbonyl oxygen atom and the positively charged oxonium carbon, or from the 1,2-neighboring participation effect that leads to the formation of 5-membered transiton states IV, VIII. Importantly, the ester function allows further elaborations to other interesting functions for synthetic applications.

CHAPTER 3

Friedel-Crafts-Prins Cascade Condensation of Propargylic Epoxides with Aldehydes
3.1 INTRODUCTION

3.1.1 Propargylic Epoxide in Organic Synthesis

Propargylic epoxides are versatile synthons for the preparations of important intermediates in modern organic synthesis. The coexistence of the triple bond and the epoxy functionality guarantees its versatilities in undergoing various chemical transformations.

Propargylic epoxides react readily with organometallic reagents to afford allenic alcohols. Normant disclosed a stereospecific method to synthesize syn and anti α-allenic alcohols from the corresponding propargylic epoxides and Grignard reagents in the presence of a Cu(I) catalyst, using the “halogen effect” to achieve the selectivity through an addition-elimination mechanism (Scheme 3.1). \(^1\) This methodology is also applicable to linear substrates with moderate to good selectivities using either Grignard or organolithium reagents.\(^1\)

\[\text{Scheme 3.1 A stereospecific synthesis of } \alpha\text{-allenic alcohol from propargyllic epoxide.}\]

In addition, Normant also developed a stereospecific approach to prepare bromoallenic alcohols using hydrobromic acid and cuprous bromide with

---

ammonium bromide as additive in aqueous media.\(^2\) 1,2-Disubstituted homopropargylic alcohols can also be readily obtained in a highly diastereoselective manner by reacting propargylic epoxides with Grignard or organolithium reagents in the presence of catalytic trifluoroborate etherate.\(^3\)

Cycloisomerization of propargylic epoxides constitutes one of the most useful methods to construct substituted furans, in which a variety of reagents activate this reaction (Scheme 3.2). When treated with catalyst PtCl\(_2\),\(^4\) iodine,\(^5\) base,\(^6\) molybdenum, and ruthenium complexes,\(^7\) substituted furans could be obtained from propargylic epoxides in an efficient manner.

**Scheme 3.2 Cyclization of propargylic epoxides to furans.**

Yoshida also developed novel palladium-catalyzed regio- and diastereoselective coupling reactions of propargylic epoxides with phenols, aryloboronic acids, carbon dioxide together with phenols, and terminal alkynes (Scheme 3.3).\textsuperscript{11}

![Scheme 3.3 Palladium-catalyzed coupling reactions of propargylic epoxides.]

Allenic ketones\textsuperscript{12} can also be easily prepared through dilithio ynenolates by the double deprotonation of propargylic epoxides. By using gold (I) catalyst, Pale disclosed a facile approach to divinyl ketones via a rearrangement of the starting propargylic epoxides.\textsuperscript{13}

![Scheme 3.4 Rearrangement of propargylic epoxides to allenic ketones.]

Propargylic epoxide also found its applications in the total synthesis of natural products. Hanaoka\textsuperscript{14} completed the first total synthesis of the highly toxic fish poison (-)-ichthyothereol and its acetate analogue with its core structure prepared through a dicobalt octacarbonyl $[\text{Co}_2(\text{CO})_8]$-mediated \textit{endo} mode cyclization of the propargylic epoxide intermediate, which was readily generated from the commercially available material, diethyl L-tartrate. This $[\text{Co}_2(\text{CO})_8]$-mediated \textit{endo} mode cyclization of propargylic epoxides could also be applied to the construction of tetrahydrofuran, tetrahydropyran, and oxepane frameworks containing a 2-ethynyl-3-hydroxy substituents as a common feature.\textsuperscript{15}

\[

2) $\text{BF}_3\cdot\text{Et}_2\text{O}$, -78 °C, 87%

Scheme 3.5 $[\text{Co}_2(\text{CO})_8]$-mediated \textit{endo} mode cyclization of propargylic epoxide.

In the total syntheses of Amphilinolide X\textsuperscript{16} and Y\textsuperscript{17}, propargylic epoxide prepared from allylic alcohol \textit{via} Sharpless epoxidation, was converted to the target tetrahydrofuran motif after further elaborations to the allenic alcohol and subsequently dihydrofuran (Scheme 3.6).

The versatility of propargylic epoxide in construction of novel structures was also elegantly demonstrated in Smith’s synthetic studies towards (+)-sorangicin A (Scheme 3.7). The novel dioxabicyclo[3.2.1]octane motif, one of the key structural features of the potent antibiotic (+)-sorangicin A, was assembled via a series of Lewis acid-catalyzed epoxide-opening cyclizations, and a higher yield and regioselectivity of the desired 6-exo-tet cyclization product was achieved by reducing the alkyne steric bulkiness, at the same time accelerating the reaction rate.

Scheme 3.7 Novel dioxabicyclo[3.2.1]octane assembled from propargylic epoxide.

3.1.2 Prins Cyclization of Homopropargylic Acohols

Besides homoallylic alcohols, homopropargylic alcohols are also useful substrates to undergo Prins cyclization with various aldehydes to afford substituted dihydropyrans in a highly stereoselective manner. Martín and Padrón developed an efficient and facile ferric halides mediated method to make 1-alkyl-4-halo-5,6-dihydropyran via Prins cyclization of primary homopropargylic alcohols (Scheme 3.8). An aza-Prins cyclization was also disclosed by Martín to synthesize the six-membered aza-heterocycles from the propargyl tosylamines and aldehydes in excellent yields.

\[
\text{Scheme 3.8 Ferric halides mediated Prins cycliation of primary homopropargylic alcohol.}
\]

However, when secondary homopropargylic alcohol was subjected to this cyclization conditions, it suffered from undesired oxonia-Cope rearrangement and a 1,3-\(O\)-transposition process to afford unexpected coupling reaction products, including unsaturated \(\beta\)-hydroxyketone and \(\alpha,\beta\)-unsaturated ketones, instead of generating the target Prins cyclization products (Scheme 3.9).

---

This problem could be effectively solved by modifying the propargylic alcohol with substituents installed either at the end of the triple bond or \( \alpha \) to the hydroxy functionality, which serve to suppress the undesired oxonia-Cope rearrangement either by stabilizing the vinyl carbocation intermediate or destabilizing the allenic species (after rearrangement in theory).\(^{22}\) Subsequently, an efficient approach was developed to generate Prins products from TMS-substituted secondary homopropargylic alcohols in excellent yields and stereoselectivity (Scheme 3.10).

Interestingly, when the homopropargylic alcohol was terminated with alkyl or aryl substituents on its triple bond, the regioselectivity in the Prins cyclization was switched from the normally preferred 6-endo type to an exclusive 5-exo cyclization mode, offering a novel approach to construct substituted tetrahydrofurans.\(^{23}\)

---

3.2 **CASCADE REACTION TO MAKE POLYCYCLIC FRAMEWORKS**

Cascade reactions become more and more appealing to synthetic chemists due to their intrinsic efficiency and elegance in building up molecular complexities, where the concurrent formation of multiple bonds and installation of multiple stereogenic centers usually occur in a highly chemo-, regio- and stereoselective manner from simple linear precursors, exhibiting numerous other impressive advantages, including atom, labor and time economy as well as less waste generation. It still remains a challenge for synthetic chemists to design and tailor substrates properly in order to enable them to undergo various chemical transformations to afford polycyclic frameworks in a diastereoselective cascade manner. Importantly, sophisticated substrate design is essential to discover new cascade reactions, and the successful executions of these cascade reactions have been elegantly demonstrated in the total synthesis of numerous natural products, such as (-)-FR-182877 and dihydroprotodaphniphyline.

To our knowledge, we found that Prins cascade reactions prove to be highly efficient in generating important intermediates in a highly regio- and stereoselective

---

way, which are of great importance in synthetic practice.\textsuperscript{26} With our understanding towards Prins cyclization,\textsuperscript{27a, b} we envisioned that cyclic propargylic alcohols would be viable substrates for Prins cyclization, which could be generated \textit{in situ} from linear propargylic epoxide via an intramolecular epoxide-opening-addition reaction (Scheme 3.12).\textsuperscript{27c,d, 30b} We also felt that by tuning the chain and the terminal nucleophile, this cascade Prins reaction would serve as a potentially useful methodology in the synthetic study towards polycyclic ethers, which are frequently occurring structural elements found in numerous marine natural products having important biological activities.\textsuperscript{28}

Scheme 3.12 Proposed Prins cascade reaction to polycyclic substituted dihydropyrans.

In our preliminary investigation towards this Prins cascade reaction, a benzene ring was selected as the terminal nucleophile for ease of handling. In this chapter, we report our newly developed Friedel-Crafts-Prins (FCP) cascade reaction as a convergent and efficient approach to generate complex polycyclic substituted dihydropyrans and furans by condensation of the linear propargylic epoxides with various aldehydes in the presence of Lewis acids.

3.3 RESULTS AND DISCUSSION

3.3.1 Fiedel-Crafts-Prins Cascade Condensation of cis-Propargylic Epoxide

Firstly, the regio- and stereoselectivity was established in the epoxide-opening Friedel-Crafts cyclization for the cis-propargylic epoxide 38 (Scheme 3.13). When 38 was treated with indium triflate catalyst, it underwent a regio- and stereoselective Friedel-Crafts cyclization to afford cyclic homopropargylic alcohol 42 in 91% as a single isomer (X-ray structure illustrated in Figure 3.1). The presence of the triple bond dictates this regioselectivity because it facilitates the delocalization of the positive charge during the epoxide-opening cyclization process.

![Scheme 3.13 Friedel-Crafts cyclization of cis propargylic epoxide.](image)

29 Our starting substrates were prepared in 5 steps as depicted as below:

In our initial efforts focused on making the target Prins cyclization products, cis-propargylic epoxide 40 was subjected to the stirred suspension of indium triflate catalyst to undergo a Friel-Crafts cyclization, followed a standard Prins cyclization procedure in the presence of aldehydes using TMSBr as a counterion (Br⁻) source.

It turned out rather sluggish for 40 to undergo the planned Friel-Crafts-Prins cascade condensation with cyclohexanecarboxaldehyde (Table 3.1, entry 1). Target polycyclic dihydropyran 43 was obtained in low yield with unexpected furan 44. Furan 44 was probably due to the undesirable rearrangement of the cyclic vinyl carbocation I,32 forming the benzylic-allylic-type carbocation II, which underwent subsequent hydride shifts and elimination steps to afford the polycyclic furan (Scheme 3.14). We proceeded to optimizing the reaction conditions such as by lowering reaction temperatures in the Prins cyclization step with prolonged reaction time, tuning acidity by changing Lewis acids from robust indium triflate to relatively milder ones (such as indium trifluoroacetate, indium bromide and so on) and even employing the so-called “β-effect” to stabilize the cyclic vinyl carbocation I using

TMS-terminated epoxide 38. However, no substantial improvements could be made either in increasing the yields or the selectivity. Only low selectivity and low conversions to the target Prins product could be achieved in spite of our efforts (Table 3.1, entries 2 to 12).

^a Epoxide 40 (0.1 mmol) was subjected to stirred suspension of In(OTf)₃ (0.02 mmol) in 2 mL CH₂Cl₂ at 0 °C for 4 hours, followed by addition of TMSBr (0.12 mmol) and corresponding aldehyde (0.1 mmol, in 1 mL CH₂Cl₂), and stirred for 6 hours. ^b Isolated yield. ^c Determined by ^d ¹H nmr. ^e Reaction time 12 hours for the Prins cyclization step. ^f Structure see X-ray of 43', 43' was obtained when 38 was subjected to the FCP reaction conditions.

As illustrated in the X-ray structure of 43', ring strain could probably be imposed on the cyclic vinyl carbocation I, which makes it unstable and short-lived, thus difficult for trapping with bromide. In contrast, the rearrangement of the cyclic vinyl carbocation I into much more stabilized benzylic-allylic-type carbocation II becomes a competitive reaction channel. The exact reasons for low yields are not clear. Other factors, such as decomposition, oligomerization and so on, may contribute to the low yields of the target polycyclic dihydropyrans.

Figure 3.2 X-ray structure of 43'.

Scheme 3.14 Proposed reaction mechanism of cis-propargylic epoxide in FCP cascade condensation.

Because substituted furans are also frequently occurring structural moieties in numerous natural products having important biological activities, and also in bulk
commodity chemicals and commercially important pharmaceuticals.\textsuperscript{34} We furthered reaction condition screening aiming to develop an efficient method to make polycyclic furans. Various Lewis acids were screened to mediate this condensation. Results are tabulated in Table 3.2.

\textsuperscript{a}Epoxide 40 (0.1 mmol, in 1 mL CH\textsubscript{2}Cl\textsubscript{2}) was added to stirred solution of Lewis acid in 1 mL CH\textsubscript{2}Cl\textsubscript{2} at room temperature, stirred for 1 hour, followed by addition of corresponding aldehyde (0.1 mmol, in 1 mL CH\textsubscript{2}Cl\textsubscript{2}) for 2 hours. \textsuperscript{b}Isolated yield. \textsuperscript{c}Determined \textsuperscript{1}H NMR. \textsuperscript{d}20 mol % acid used. \textsuperscript{e}without using TMSBr. \textsuperscript{f}100 mol % acid used. \textsuperscript{g}50 mol % acid used. \textsuperscript{h}120 mol % TMSBr used. \textsuperscript{i}200 mol % TMSBr used.

Interestingly, trifluoroborate etherate (BF\textsubscript{3}Et\textsubscript{2}O), TMSOTf and In(OTf)\textsubscript{3} were not efficient enough to generate the desired polycyclic furan 44 in high yields (Table 3.2 entries 1 to 4), while a combination of stoichiometric amount of indium triflate

FRIEDEL-CRAFTS-PRINS CASCADE CONDENSATION OF PROPARGYLIC EPOXIDES WITH ALDEHYDES

with excess TMSBr was found to efficiently generate the target furans in good yields at room temperature (Table 3.2, entry 7). Satisfactory results from condensation of 40 with various aldehydes are tabulated in Table 3.3. This condensation fails to afford the corresponding furans when using benzaldehyde and cinnamaldehyde. By installing a strong electron-withdrawing substituent on the phenyl ring, we did manage to obtain the corresponding furan in moderate yield (Table 3.3 entry 8). When hydrocinnamadehyde was subjected to this FCP reaction, a mixture of novel polycyclic tetrahydrofurans 50 was isolated in 70% yield, as illustrated in Figure 3.5. The reaction could be rationalized as a 5-exo type cyclization of the triple bond onto the oxocarbenium followed by a second intramolecular Friedel-Crafts addition to the vinyl carbocation which was generated in situ (Scheme 3.15).

FRIEDEL-CRAFTS-PRINS CASCADE CONDENSATION OF PROPARGYLIC EPOXIDES WITH ALDEHYDES

Interestingly, in our screening of Lewis acids to generate polycyclic furans, a [3+3]-type annulation product 45 was isolated as a single isomer with amazing molecular complexity when using stoichiometric amount of trifluoroborate etherate (BF₃·Et₂O). A certain amount of 45 could also be observed when excess indium triflate was used to mediate this condensation (Table 3.2, entries 2 and 5). The structure of 45 was established from the X-ray structure of 56 (isolated in 18% yield as a single isomer) when 2-ethylbutyraldehyde was used to run this annulation reaction.

Upon closer examination, we infer that 45 could have originated from 44 because the lower part of 45 shared the same structural features. This structural feature prompted us to conceive the reaction mechanism and led us to believe that transient cyclic vinyl carbocation I and the benzylic-allylic type carbocation II played a central role in the whole cascade process (Scheme 3.14).

We envisage that at a certain threshold after initial generation of 44, reaction intermediate II (Scheme 3.14) was trapped by 44 and finally converted to 45 after subsequent transformations, such as multiple hydride shift and aromatization process. In order to confirm our hypothesis, we designed a reaction approach to make crossed
[3+3] annihilation products with different terminal substituents (Scheme 3.16). In this design, we planned to use the parent polycyclic furan that was preformed from a different aldehyde (R’CHO), to trap the reaction intermediate II generated *in situ* from the condensation of starting *cis*-epoxide 40 with aldehyde RCHO. If the desired crossed [3+3] annihilation product could be formed as expected, we would then be able to give a plausible interpretation towards our FCP cascade reaction at a mechanistic level, which is quite important to obtain a thorough understanding towards this FCP cascade reaction.

Gratifyingly, our daring interpretation was verified by our success to make desired crossed [3+3] annihilation products 57-60. Results are shown in Table 3.4.

**Table 3.4 BF₃·Et₂O-mediated FCP cascade condensation to crossed [3+3] annulated furans.**

*a Isolated yield. b Epoxide 40 (0.1 mmol) was treated with BF₃·Et₂O (0.1 mmol) in CH₂Cl₂ at room temperature for 1 hour followed by adding the preformed polycyclic pyran (0.1 mmol), and the aldehyde was added slowly over 15 minutes, reaction was allowed to proceed at room temperature for 3 hours before quenching with saturated NaHCO₃ solution.

Crossed [3+3] type annihilation reveals the reaction mechanism of this Friedel-Crafts-Prins cascade condensation (Scheme 3.17). Cyclic homopropargylic alcohol is
smoothly generated \textit{in situ} as reaction intermediate. In the following Prins cyclization,
the distorted configuration of \textbf{I} imposes ring strain on \textbf{I} that diminishes its stability
and its lifespan, thus the difficulty in generating the desired polycyclic dihydropyrans.
Instead, rearrangement of \textbf{I} to \textbf{II} predominates, affording polycyclic furan 44. At a
certain concentration threshold, 44 undergoes an electrophilic addition onto the 3-
position of intermediate \textbf{II} to afford \textbf{III}, followed by a furan ring opening\textsuperscript{7} and a
Michael-type nucleophilic addition to intermediate \textbf{IV}. A highly complicated [3+3]
type annulation product 45 was finally generated from intermediate \textbf{IV} after
undergoing elimination and subsequent 1,3- and 1,5- hydride shifts. Another novel
structure 46 is believed to be generated from the further Fridel-Crafts addition of 44 to
the cyclohexanecarboxaldehyde followed with a dehydration step in the presence of
robust TMOTf acid.

3.3.2 Friedel-Crafts-Prins Cascade Condensation of \textit{trans}-Propargylic Epoxide

In sharp contrast to the complicated situation of FCP cascade condensation of 40, \textit{trans} propargylic epoxide 41\textsuperscript{29} proves to be a straightforward substrate for this FCP cascade condensation to afford target polycyclic pyrans in good yields with excellent stereocontrol. Results are summarized in Table 3.5. Rearrangement of cyclic vinyl carbocation intermediate to furans could be effectively suppressed by running Prins cyclization at -20 °C (Table 1, entries 1 and 2). This condensation also failed to afford the desired polycyclic pyrans from benzaldehyde and cinnamaldehyde. We managed to make the polycyclic pyran by using \textit{m}-nitro benzaldehyde in good yield (X-ray structure shown in Figure 3.7), where the strongly electron-withdrawing substituent activates the aldehydic functionality (Table 3.5, entry 9). However, no reaction was observed for conjugate aldehydes, including cinnamaldehyde and \textit{p}-nitro-cinnamaldehyde.

We infer that it is probably due to the stability of the intermediate V, which allows efficient trapping by bromide anion rather than rearranging to benzylic-allylic type carbocation II (Scheme 3.18). In contrast to I, rearrangement of V to the polycyclic furans could be effectively suppressed by lowering the reaction temperatures (Table 3.5 entry 2).

3.4 CONCLUSION

In conclusion, a novel Lewis acid catalyzed (mediated) Friedel-Crafts-Prins cascade condensation reaction of propargylic epoxides with various aldehydes has been developed which allows us to make a series of complex polycyclic dihydropyrans and polycyclic furans in a convergent and efficient manner. This Friedel-Crafts-Prins cascade condensation shows the following main features: (1) the π-orbital on the triple bond assists the regioselective epoxide-opening Friedel-Crafts cyclization reaction, (2) relative stereochemistry of the propargylic epoxide controls the stereochemical outcome of the intermediate cyclic homopropargylic alcohol; (3) Prins cyclization affords the desired polycyclic substituted dihydropyrans as a single
diastereoisomer from trans-propargylic epoxide. However, cyclic vinyl carbocation rearrangement predominated and afforded polycyclic substituted furans as major products from the cis-propargylic epoxide.

In addition, this Friedel-Crafts-Prins cascade reaction also provides an excellent occasion for probing reaction mechanisms by controlling reaction conditions. It also offers a clear vision towards the importance of substrates design in discovering new cascade reactions.
CHAPTER 4

Friedel-Crafts-Prins Cascade Condensation of Allylic Epoxides with Aldehydes
4.1 INTRODUCTION

4.1.1 Allylic Epoxide in Organic Synthesis

Allylic epoxide is an important structural moiety observed in many natural products having remarkable biological activities (Figure 4.1). Examples include algal pheromones lamoxirene, caudoxirene, biosynthetic precursor to leukotriene, and macrocyclic lactones.¹

![Figure 4.1 Natural products possessing allylic epoxide moiety.](image)

Allylic epoxides are also important intermediates in modern organic synthesis. It is well established that allylic epoxide could be utilized as electrophile in intramolecular carbocyclization reactions with enolate derivatives. The Stork cyclization is a typical demonstration of this strategy to form cyclohexane systems with complete control of regiochemistry and stereochemistry via the intramolecular cyclization of allylic epoxide.² In addition, this stereocontrolled enolate alkylation reaction found its application in the total synthesis of (−)-terpestacin and (−)-fusaproliferin, although with undesirable stereochemical outcome in terms of the double geometry (Scheme 4.1).³

Scheme 4.1 Regio- and diastereoselective intramolecular carbocyclization of allylic epoxide.

In the synthetic studies towards the total synthesis of Brevetoxin A, Nicolaou developed a novel strategy to construct medium-sized cyclic ether via a regio- and diastereoselective intramolecular hydroxy-epoxide-opening cyclization of allylic epoxide (Scheme 4.2). The incorporation of a double bond adjacent to the epoxide function determines the 6-endo cyclization mode due to its facilitation of the delocalization of partial positive charge generated in situ during the cyclization process. This type of cyclization was also observed by Nakata under acidic or basic conditions, and by Somfai for an internal Friedel-Crafts type addition catalyzed by Lewis acid.

\[ \text{CH}_2\text{Cl}_2, 0^\circ\text{C, 15 min} \]
\[ 91\% \]

Scheme 4.2 Regio- and diastereoselective intramolecular hydroxy-epoxide-opening cyclization.

On the other hand, the intermolecular version of the nucleophilic addition occurred in a divergent manner, and both \( S_N2 \) and \( S_N2' \) type adducts could be observed during epoxide-opening. For electronic stabilization reasons, epoxide is

---

normally cleaved at the allylic position and attacked by hard nucleophiles to afford $S_N2$ type adduct, while for bulky soft nucleophiles, $S_N2'$ attack is preferred.\(^6\)

Regioselective addition could be realized by controlling the reaction conditions, for instance, a combination of lithium ethoxyacetylides and BF$_3$OEt$_2$ afforded $S_N2$ displacement, whereas $S_N2'$addition predominated when alkynylalanes was utilized (Scheme 4.3).\(^6\)

Scheme 4.3 Regio-selective and divergent epoxide-opening of allylic epoxide with nucleophiles.

Allylic epoxides also serve as excellent electrophiles in transition metal-catalyzed carbon-carbon coupling reactions, such as palladium-catalyzed alkylation and arylation of allylic epoxides with various nucleophiles (Scheme 4.4).\(^7\)

Scheme 4.4 Palladium-catalyzed coupling reaction of allylic epoxide with nucleophiles.

In addition, Lewis acid-catalyzed stereospecific rearrangement of optically pure tertiary allylic epoxides offers a rapid access to chiral quaternary aldehydes, which are important precursors for the synthesis of biologically active compounds,

such as α-alkyl amino aldehydes and acids (Scheme 4.5).\(^8\) Recently, Njardarson\(^9\) described a novel method to synthesize a series of 3,4-dihydrofurans via copper(II) complex-catalyzed rearrangement of allylic epoxides, which is elegant and appealing due to the low catalyst loading, broad tolerance of substitution patterns and solvent-free manner.

![Scheme 4.5 Rearrangement of allylic epoxides to novel structures.](image)

### 4.1.2 Fused Bicyclic and Polycyclic Tetrahydropyran Systems

Substituted tetrahydropyran rings are ubiquitous structural features frequently encountered in numerous natural products possessing potent biological activities.\(^10\)

Both cis- and trans-fused bicyclic or polycyclic tetrahydropyran ring systems are also frequently occurring in a wide range of biologically active natural products, such as (3Z)-dactomelyne, (3E)-dactomelyne,\(^11\) thyrsiferol,\(^12\) okadaic acid,\(^13\) and so on\(^14\)

---

FRIEDEL-CRAFTS-PRINS CASCADE CONDENSATION OF ALLYLIC EPOXIDES WITH ALDEHYDES

(Figure 4.2). Considerable efforts have been stimulated in the synthetic community, and many elegant methods have been devised towards synthesis of these challenging structures.\textsuperscript{11-14} However, most of these syntheses rely on iterative or reiterative strategies in which one cyclic tetrahydropyran ring is constructed over a series of chemical transformations in a stepwise manner.\textsuperscript{11-14, 15}

An iterative radical cyclization strategy was adopted to form the \textit{cis}-fused bicyclic tetrahydropyran ring skeleton in the total synthesis of marine natural product, (3\textit{Z}) and (3\textit{E})-dactomelyne.\textsuperscript{16} Lee\textsuperscript{11} developed a highly stereoselective radical cyclization using the \textit{β}-alkoxyacrylates twice as radical acceptors for the introduction of alkyl and halogen substituents onto the pyranopyran ring system (Scheme 4.6).

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure4.2}
\caption{Natural products possessing bicyclic tetrahydropyran rings.}
\end{figure}

Scheme 4.6 Double radical cyclization of \textit{β}-alkoxyacrylates to \textit{cis}-fused bicyclic THP ring skeleton.

\begin{flushright}
\textsuperscript{15} Nakata, T. \textit{Chem. Rev.} \textbf{2005}, 105, 4314. (b)
\end{flushright}
Similarly, bicyclic and polycyclic tetrahydropryan ring systems could also be generated through iterative 6-endo-mode hydroxy-epoxide-opening cyclization with the assistance of π-orbital (Scheme 4.3)\textsuperscript{4} or TMS substituent (Scheme 4.7).\textsuperscript{17} Such strategy proves to be quite effective for formation of the bicyclic THP skeleton in the total synthesis of thyrisferol and its analogues.\textsuperscript{18}

By controlling the reaction conditions, the intramolecular allylation of internal aldehyde with allylstannanes,\textsuperscript{19} allylsilanes,\textsuperscript{20} and alkoxyallylboranates\textsuperscript{21} also constitute one effective approach to selectively form both cis- and trans-linked bicyclic- and tricyclic- tetrahydropyran rings (Scheme 4.8).

\textsuperscript{17} Heffron, T. P.; Jamison, T. F. \textit{Org. Lett.} 2003, 5, 2339.

\textsuperscript{18} Gonzaléz, I. C.; F. G.; Forsyth, \textit{J. Am. Chem. Soc.} 2000, 122, 9099. (b)

Another approach is the intramolecular Michael-addition of an alcohol to an internal $\alpha,\beta$-unsaturated ester\(^{22}\) or stereoselective mercuricyclization of hydroxyl group onto an internal double bond (Scheme 4.9).\(^{23}\)

![Scheme 4.9 Double iterative intramolecular stereoselective mercuricyclization.](image)

Some other type iterative approaches to trans-fused THP ring systems have also been reported, including the reiterative coupling reaction of C\(_3\) oxiranyl anion followed with a 6-endo cyclization,\(^{24}\) or through stereoselective generation and rearrangement of cyclic oxonium ylide [2,3]-shift in an iterative manner (Scheme 4.10).\(^{25}\)

**Scheme 4.10 Iterative oxiranyl anion coupling-cyclization and oxonium ylide [2,3]-shift approaches.**

Importantly, trans-fused bicyclic THP ring skeleton could also be formed via the intramolecular sily-modified Sakurai condensation (ISMS) of vinylsilanes followed with further elaborations (epoxidation and cyclization) in a stepwise manner (Scheme 4.11).\textsuperscript{26}

  \draw[->] (C) -- (I);

\end{tikzpicture}
\end{center}

Scheme 4.11 Iterative intramolecular silyl-modified Sakurai condensation of vinylsilane.

Despite the effectiveness and elegance of these iterative approaches to such bicyclic and polycyclic cis- or trans-fused tetrahydropyran ring systems, interest and demand for novel and facile methods for rapid access to these motifs remain unabated.\textsuperscript{27} Cascade epoxide-opening cyclization reaction is of great superiority as compared to those iterative approaches because of its intrinsic efficiency and elegance in rapidly building up the polycyclic tetrahydropyran frameworks with high regio- and stereoselectivities. Jamison described a highly elegant biomimic synthesis of ladder ether ring skeleton via an epoxide-opening cyclization cascade using water as both the solvent and promoter (Scheme 4.12).\textsuperscript{26b}

\begin{footnotes}
\textsuperscript{26} Markó, E. I.; Dobbs, A. P.; Scheirman, V.; Chellé, F.; Bayston, D. J. \textit{Tetrahedron Lett.} 1997, 38, 2899.
\end{footnotes}
It is self-evident that cascade reaction exhibits appealing advantages for construction of polycyclic tetrahydropyrans, which is highly impressive to synthetic chemists. In our group a long-lasting interest has been ongoing towards the development of novel methodologies for the synthesis of various THP-containing compounds. Our previous studies revealed that linear homoallylic alcohols are excellent substrates to undergo Prins cyclization with various aldehydes to afford 2,6-cis-4-halo-trisubstituted tetrahydropyrans in a highly stereoselective manner. We envisaged that cyclic homoallylic alcohols should also be excellent substrates to undergo Prins cyclization with aldehydes. We also felt that it would be a facile and rapid approach to make bicyclic THP ring system in one-pot manner: Lewis acid catalyzed epoxide-opening cyclization to generate the cyclic homoallylic alcohol in situ, followed with a Prins cyclization operation to construct the second THP (Scheme 4.13).
In this chapter, we report our novel, efficient and convergent indium triflate catalyzed Friedel-Crafts-Prins (FCP) cascade condensation of allylic epoxides with aldehydes to construct complex polycyclic tetrahydropyran rings in a rigio- and stereoselective manner. Both cis- and trans-allylic epoxides terminated with phenyl ring were prepared as our starting materials for this FCP cascade reaction.29

4.2 RESULTS AND DISCUSSION

4.2.1 Friedel-Crafts-Prins Cascade Condensation of cis-Allylic Epoxide

In the beginning, cis-allylic epoxide 72 was first selected to test our designed FCP cascade reaction. Epoxide 72 was subjected to the vigorously stirred suspension of indium triflate catalyst in dichloromethane at 0 °C for 2 hours to generate the reaction intermediate (cyclic homoallylic alcohol) in situ through a epoxide-opening Friedel-Crafts cyclization, followed with addition of the additive TMSBr and the corresponding aldehydes to undergo the Prins cyclization reaction. To our delight, this FCP cascade reaction proceeded smoothly in a highly efficient and stereoselective manner to afford our desired polycyclic tetrahydropyran in good yield as a single diastereoisomer. Results are tabulated in Table 4.1. The stereochemistry was determined and further confirmed by the X-ray crystal structure of 80 (Figure 4.3), with all stereogenic centers installed as expected.

---

29 Our starting materials, cis- and trans-allylic epoxides were prepared from the corresponding propargylic epoxides, respectively.

4.2.2 Friedel-Crafts-Prins Cascade Condensation of *trans*-Allylic Epoxide

With the exciting results obtained from our FCP cascade condensation of *cis*-allylic epoxide 72 with various aldehydes, we moved to run this condensation using *trans*-isomer 73 under the same sequential reaction conditions. Epoxide 73 was converted to the *trans* cyclic homoallylic alchol upon treatment with indium triflate catalyst, and the target condensation products were formed smoothly after the subsequent Prins cyclization reaction in the presence of slightly excess TMSBr as counterion (Br\(^-\)) source. As expected, *trans*-isomer 73 proved to be an excellent substrate for this FCP cascade condensation. Desired polycyclic tetrahydropyrans could be synthesized through this cascade condensation in good yields as a single isomer, whose stereochemistry was clearly illustrated in the X-ray crystal structure of 85 (Figure 4.4). Results are summarized in Table 4.2.

4.2.3 Mechanistic Interpretation of Friedel-Crafts-Prins Cascade 

Condensation of cis- and trans-Allylic Epoxides 

As shown in scheme 4.14, a mechanistic interpretation could be deduced from our experimental results. When treated with the vigorously stirred suspension of indium triflate catalyst in dichloromethane at 0 °C, allylic epoxides, cis-isomer 72 and trans-isomer 73 underwent a regio- and stereoselective epoxide-opening-Friedel-Crafts cyclization with the assistance of the π-orbitals on the double bond, and were transformed into the corresponding cyclic homoallylic alcohols respectively. After the introduction of aldehyde and slightly excessive TMSBr as counterion source, Prins cyclization occurred smoothly between the cyclic homoallylic alcohols and aldehydes to afford cyclized polycyclic tetrahydropyrans with excellent stereocontrol. In each case, only one single diastereoisomer was obtained, as evidenced by the respective X-ray structure (Figure 4.3, and Figure 4.4).

Scheme 4.14 Proposed reaction mechanism of Friedel-Crafts-Prins condensation of cis- and trans-allylic epoxides with aldehydes.
4.2.4 Prins Cascade Condensation of Allylic Epoxide with Hydroxy Function as Terminal Nucleophile

We also attempted to make bicyclic tetrahydropyrans by utilizing allylic epoxides containing a hydroxyl function as the terminal nucleophile. However, initial results revealed that In(OTf)$_3$, InBr$_3$, TMOTf were not competent catalysts for this cascade reaction, and only partially cyclized product 92 could be isolated in low yields (~ 30%) without any formation of desired bicyclic THP rings.

The reaction still proved quite sluggish even when following a reported method$^4$ to generate the reaction intermediate 92 \textit{in situ}, followed with a subsequent Prins cyclization step using stoichiometric amount of TiCl$_4$ as promoter, affording target 91 in around 18% yield. Unexpectedly, it was found that the inefficient epoxide-opening cyclization should be responsible for the overall low efficiency of this cascade condensation, where only 33% of 92 could be isolated in a separate operation by treating 90 with camphorsulphonic acid. Our finding towards this low yield problem was consistent with Hoffmann’s observations.$^{11c}$ Thus, we infer that the Prins cyclization should still be efficient for transforming 92 into the target bicyclic THP ring 91 in an estimated yield of around 60%.

![Scheme 4.15 Synthesis of bicyclic THP ring via Prins cascade condensation.](image-url)
4.3 CONCLUSION

In conclusion, we have developed a novel, efficient Friedel-Crafts-Prins cascade condensation reaction of allylic epoxides with various aldehydes catalyzed by indium triflate. The target polycyclic tetrahydropyrans were convergently synthesized from condensation of the corresponding allylic epoxide and aldehydes in a highly regio- and diastereoselective manner.

The main features of this reaction are as follows: (1) the regioselectivity in the epoxide-opening cyclization is assisted by the π-orbitals on the double bond, and the stereochemical outcome of the cyclization was controlled by the starting allylic epoxides; (2) desired polycyclic tetrahydropyrans are formed via Prins cyclization in a diastereoselective manner as a single isomer.

Although our preliminary attempts to apply this reaction to construct the bicyclic THP ring system were unsuccessful due to the substrate problem, this could be overcome by substrate design, because it was revealed that the Prins cascade reaction itself is still an efficient approach with finely tailored substrates. Therefore, this catalytic, diastereoselective Prins cascade condensation reaction is of both academic importance and practical values.
CHAPTER 5

Prins Cyclization of Allenic Alcohols and Synthetic Study towards (+)-Sambutoxin
5.1 **Introduction**

5.1.1 Dihydropyran (DHP) Rings in Natural Products

Dihydropyran (DHP) rings are core structural features found in natural products having important biological activities, such as jerangolid A, B, C, and D,\(^1\) funiculosin, \(^2\) (+)-ambruticin, \(^3\) (+)-4,5-deoxyneodolabelline, \(^4\) and methyl sarcophytoate (Figure 5.1).\(^5\) These DHP backbones are attractive targets for synthetic chemists to devise novel methodology aimed at the efficient syntheses of the natural toxins, which are potential pharmaceutical candidates.

![Figure 5.1 Natural products containing dihydropyran (DHP) ring backbones.](image)

5.1.2 Development of Novel Prins Cyclization for DHP Synthesis

Based on our knowledge accumulated from our previous investigations towards Prins cyclization, we envisage that it would be an interesting and promising process to construct dihydropyrans using allenic alcohols as starting material (Scheme

5.1. This novel strategy would probably open a rapid and facile access to the dihydropyran backbone, which is highly valuable for synthetic purposes as inspired by the natural toxins with DHP backbones (Figure 5.1).

![Scheme 5.1 Proposed protocol of Prins cyclization of allenic alcohols.](image)

However, it still remains a great challenge to use allenic alcohols to do Prins cyclization reaction, and quite little has been documented in this area.

To the best of our knowledge, only some Prins-type cyclizations of homoallenyl alcohols have been reported for the construction of functionalized oxaheterocycles, including tetrahydropyrans, tetrahydrofurans and tetrahydrooxepines (Scheme 5.2).  

![Scheme 5.2 Prins-type cyclization of homoallenyl alcohols with aldehydes.](image)

---

7 (b) Chan, K. P.; Loh, T. P. *Org. Lett.* 2005, 7, 4491.  
One strategy developed by Cho, was the reaction of homoallenyl alcohols with aldehydes using TMSOTf as a promoter via a 6-exo mode cyclization to form 2,6-disubstituted-3,4-dimethylidene tetrahydropyrans.\(^7\) The other strategy reported by Yu, was achieved through the Prins cyclization of homoallylic alcohol intermediate, which was generated in situ through palladium-complex assisted rearrangement of the homoallenyl alcohol in the presence of organostannane, affording the tetrahydrofurans.\(^10\) Tetrahydrooxepines were obtained due to isomerization of the trimethyltin-substituted homoallylic alcohol when this reaction was performed in dichloromethane (Scheme 5.2).\(^8\)

In an earlier separate account, Yu described a pioneer strategy aimed at synthesizing tetrahydropyranone via Prins-type cyclization of allenic alcohols with aldehydes using Lewis acid promoters (Scheme 5.3).\(^9\) In spite of their efforts in surveying various reaction conditions, such as using different Lewis acids, including In(OTf)\(_3\), TMSOTf, TMSNTf\(_2\), BF\(_3\)Et\(_2\)O, Sc(OTf)\(_3\), Zn(OTf)\(_2\), MgCl\(_2\), HgCl\(_2\) and so on, their strategy failed to form the target tetrahydropyranones, which was rationalized as due to the lack of reactivity of the allenic alcohols. Instead, coupling products were obtained as the major outcome when this reaction was mediated by stoichiometric amount of InCl\(_3\) as a promoter at room temperature in dichloromethane. This coupling reaction readily afforded (E)-hydroxyenones as the major coupling products which are reminiscent of a convenient combination of both Wittig reaction and aldol reaction generated in an one-pot manner via a 1,3-O-transposition process. In addition, a trace amount of conjugated ketones were also observed as a side

---

product in their studies which was thought be derived directly from the allenic alcohols via a 1,3-O-transposition process.

\end{align*}
\]

Scheme 5.3 Yu’s attempts to develop a novel Prins cyclization of allenic alcohols.

In contrast to Yu’s findings, our group recently disclosed a novel \textit{trans} Prins cyclization method for synthesizing 2,6-\textit{trans}-disubstituted-4-halo-3,4-dihydropyrans by subjecting allenyl alcohol bearing α-alkoxycarbonyl group to Prins cyclization conditions (Scheme 5.4).\textsuperscript{10} High 2,6-\textit{trans} diastereoselectivity (> 86:14) was achieved for methyl-substituted allenyl alcohol bearing α-alkoxycarbonyl group, and was further enhanced to up to > 99:1 when using TMS substituted allenyl alcohol bearing α-alkoxycarbonyl group. The α-alkoxycarbonyl group adjacent to the allenyl alcohol motif played an essential role for the success of this 2,6-\textit{trans}-diastereoselectivity: suppressing undesired oxonia-Cope rearrangement \textsuperscript{11} and directing the α-alkoxycarbonyl group to adopt an axial orientation through stereoelectronic interaction between the lone pair on the carbonyl oxygen and the partially positive-charged oxonium carbon.

\]

Scheme 5.4 \textit{trans}-Prins cyclization of alkoxy-allenic alcohols with aldehydes.

However, prior to utilizing allenyl alcohol bearing α-alkoxycarbonyl group as the starting substrate, the oxonia-Cope rearrangement was encountered as a great setback (Scheme 5.1) during our initial stage for developing a novel Prins cyclization using common allenyl alcohols that do not bear α-alkoxycarbonyl group. Under standard Prins cyclization conditions developed in previous studies, our strategy (Scheme 5.1) was severely disturbed by the undesirable side reaction originating from the facile oxonia-Cope rearrangement, in which homopropargylic transfer process predominated leading to the formation of undesired DHP ring (Scheme 5.5).

With our previous experience and success in suppressing the epimerization by tuning reaction temperature and Lewis acidity, where mild Lewis acidity serves to retard the undesired allyl transfer process, we felt that it may be feasible to find the optimal reaction conditions by controlling the reaction temperatures, catalyst loading, and Lewis acidity.

In this chapter, we further our investigations in spite of the difficulties as mentioned above, aiming to developing a novel cis Prins cyclization using common allenic alcohols. The justification for development of this novel cis Prins cyclization of common allenic alcohols also comes from our synthetic interests towards

PRINS CYCLIZATION OF ALLENIC ALCOHOLS AND SYNTHETIC STUDY TOWARDS (+)-SAMBUTOXIN

Funiculosin and (+)-Sambutoxin. Some progress has been achieved in developing this novel cis Prins cyclization using common allenic alcohols by effective suppression of the undesired oxonia-Cope rearrangement through a careful survey of reaction conditions, and the substrates factors have also been taken into account.

5.2 RESULTS AND DISCUSSIONS

5.2.1 cis Prins Cyclization of TMS-substituted Allenic Alcohols

We ran the Prins cyclization (Scheme 5.1) reaction at lower temperatures and at reduced concentrations, which was based on the empirical knowledge gained in suppressing the epimerization problem encountered in previous synthetic study towards (-)-Centrolobine.6b

The TMS-substituted allenic alcohol 93 was used as starting material to run Prins cyclization with cyclohexanecarboxaldehyde at -78 °C in dichloromethane. Different Lewis acids were screened for promoting this cyclization and results are summarized in Table 5.1. It could be seen that for robust Lewis acids, such as In(OTf)3, TMSOTf, and InBr3, the oxonia-Cope rearrangement process could not be effectively suppressed (Table 5.1, entries 1-3). To our delight, indium trifluoroacetate was found to be the suitable Lewis acid, where its mild acidity promoted the Prins cyclization smoothly at -78 °C over 18 hours with effective suppression of the undesired side reaction (Table 5.1, entries 5 and 6). It was also found that this Prins reaction was most efficiently promoted in terms of atom economy by 20 mol % In(tfa)3 with 1.2 equivalent of TMSBr as additive (Table 5.1, entry 5) in dichloromethane over 18 hours to afford our desired crossed 2,6-cis-disubstituted-4-bromo-dihydropyran product in 81% yield as a single diastereoisomer without any observation of the 2,6-trans-dihydropyran diastereoisomer. However, it failed to
generate the desired product when this model Prins cyclization was performed at 0 °C, giving an intractable mixture (Table 5.1, entry 7). Thus, it could be seen that the low reaction temperature is essential for this reaction, and milder acidity helps to suppress the undesired oxonia-Cope rearrangement effectively.

*Concen. denotes concentration of 93 with respect to CH₂Cl₂ in mol L⁻¹. *b* isolated yields. *c* Reaction was done at 0 °C for 18 h.

Under optimal reaction conditions, we explored the scope of this cis Prins cyclization by reacting the TMS-substituted allenic alcohol 93 with various aldehydes. Results are summarized in Table 5.2. Desired crossed 2,6-cis-disubstituted-4-bromo-dihydropyran products were obtained in moderate to good yields with excellent diasteroselectivity. Aliphatic aldehydes were found to react readily with the allenic alcohol to afford the target products in good yields, while
PRINS CYCLIZATION OF ALLENIC ALCOHOLS AND SYNTHETIC STUDY TOWARDS (+)-SAMBUTOXIN

Aromatic aldehydes are less reactive resulting in a lower yield. No reaction could be observed for conjugated aldehydes in this Prins cyclization.

5.2.2 cis Prins Cyclization of Methyl-substituted Allenic Alcohols

With the success in performing the cis Prins cyclization using the TMS-substituted allenic alcohol 93, we progressed to extend this Prins cyclization to methyl-substituted allenic alcohol 104 (Scheme 5.6). Under the optimal reaction conditions as described above, a mixture of 105 and 106 was obtained in a combined yield of 82% with a ratio of 52:48 (105:106).

![Scheme 5.6 Prins cyclization of Me-substituted allenic alcohol 104 with cyclohexanecarboxaldehyde.](image)

This outcome was beyond our expectation that at -78 °C indium trifluoroacetate failed to afford our desired crossed 2,6-cis-disubstituted-3-methyl-4-bromo-dihydropyran as the major product. It turned out to be futile despite our efforts to optimize this reaction, such as slow introduction of the Me-substituted allenic alcohol 104 via using syringe pump, and using excess TMSBr (3.0 equiv.) aiming for more efficient trapping of the cationic reaction intermediate, dihydropyranyl carbocation.\(^\text{13}\) We speculate over this phenomenon and that this cyclization could probably be interfered again by the undesired oxonia-Cope rearrangement process: the conversion from the transition state I to II. Here we rationalized our observations by invoking such a hypothesis that dihydropyran product 105 could be generated either from transition state I (path I) or transition states II (path II), while 106 should only be formed through transition states II (path III) (Scheme 5.7). It seems that this hypothesis is somewhat plausible because we observed similar results when stronger

acids like In(OTf)₃ and InBr₃ were utilized to promote this reaction (Table 5.3, entries 2 and 3). As expected, no improvements could be achieved at -40 °C (Table 5.3, entries 5 to 7), and decompositions of allenic alcohols 104 occurred at elevated temperatures (Table 5.3, entries 8 to 13).

a Ratio determined by ¹H nmr spectrum, combined yield for entry 1 was 82%, yields were not determined for other tests. b TMSCl was used as additive. c N. R. denotes no reaction with the recovery of starting materials. d Decomposition of the starting Me-substituted allenic alcohol 104 occurred without any formation of desired dihydropyran products.
5.2.3 Prins Cyclization of Acetyl Allenic Alcohol

From a mechanistic point of view, we are highly interested in deciphering the reasons for the different outcome when we changed the starting TMS-substituted allenic alcohol 93 into Me-substituted allenic alcohol 104 under the same cyclization conditions. We infer that the transition state II (T. S. II) is probably favored because of its lower energy as compared with transition state I (T. S. I) (Scheme 5.7), resulting in the facile occurrence of the undesired oxonia-Cope rearrangement. We wonder whether this rearrangement could be suppressed by incorporating an electron-withdrawing group (EWG) adjacent to the hydroxyallenyl moiety (Scheme 5.8).

Scheme 5.8 Prins cyclization of Me-substituted allenic alcohol with aldehydes.

Me-substituted allenic alcohols 107 were prepared for testing our planned protocol by installing a protected hydroxyl group, including –OTIPS, -OTBDMS, -OBn, which is placed adjacent to the hydroxyallenyl function. We envisage that the electronegative oxygen atom would disfavor the formation of T. S. II type species (Scheme 5.7), helping to suppress the undesired oxonia-Cope rearrangement during cyclization.

Unfortunately, this strategy failed to afford our desired products. Only negative results were observed, such as no reaction, decomposition of starting allenic alcohols, or intractable reaction crude, in spite of our attempts in screening the reaction conditions, including using different Lewis acid promoters, running this cyclization reaction at different temperatures (from -78 °C to room temperature), and using different additives as counterion source (Table 5.4).

*Messy reaction crude observed. b starting material decomposed. N. R. denotes no reaction occurred with starting materials recovered. d 1.0 equiv. of 2,6-di-tert-butylpyridine added as proton scavenger.

Despite of the negative results observed above, we furthered our study by incorporating a carbonyl function nearby the hydroxyallenyl moiety as the electronic withdrawing group (Scheme 5.9). We planned to use methyl-substituted acetyl allenic
alcohol 109\(^{14}\) to conduct this Prins cyclization with aldehydes by exploiting the carbonyl function to suppress the undesired oxonia-Cope rearrangement. In addition, this *cis* Prins cyclization methodology development here exploiting acetyl allenic alcohol also serves as a model study for our synthetic studies towards Funiculosin and (+)-Sambutoxin.

![Scheme 5.9 Prins cyclization of acetyl allenic alcohol 109 with aldehydes.](image)

We continued to screen the reaction conditions by subjecting the acetyl allenic alcohol 109 and 2-ethyl-butylaldehyde to Prins cyclization conditions using different Lewis acid promoters. Our preliminary observations revealed that the acetyl allenic alcohol 109 exhibited low reactivity over aldehyde in this Prins cyclization at low temperatures. No reaction could be observed at low temperatures (-78 °C and -60 °C) in dichloromethane with a variety of Lewis acid promoters in either catalytic or stoichoimetric amounts, including In(OTf)_3, TMSOTf, TMSNTf_2, Sn(OTf)_2, La(OTf)_3, Sc(OTf)_3, In(tfa)_3, InBr_3, InCl_3, TiCl_4, AlCl_3, SnCl_4, and BF_3·OEt_2 with either TMSBr or TMSCl as additive. At elevated temperatures (such as -40 °C, 0 °C, and room temperature), strong Lewis acids, such as In(OTf)_3, TMSOTf, TMSNTf_2, La(OTf)_3, In(tfa)_3, InBr_3, and BF_3·OEt_2 caused the decomposition of the starting acetyl allenic alcohol 109 without any formation of the target dihydropyran products.

After screening numerous reaction conditions, we came to several key findings: 1) InCl_3 was found by far, to be the most suitable Lewis acid for promoting

\[\text{Prins Cyclization of Allenic Alcohol} 109\]

---

\(^{14}\) Me-substituted allenic alcohol 109 was prepared as follows:

![Image of reaction scheme](image)
this Prins cyclization, which is superior in terms of forming our desired dihydropyrans, and thus was selected for further systematic studies; 2) TMSCl is superior to TMSBr as counterion source, because TMSBr caused decomposition of the starting alcohol 109; 3) the cyclization reaction turned out to be sluggish when InCl₃ was used in catalytic amount at both room temperature and 0 °C even with prolonged reaction time; 4) in terms of chemical yields and reaction rate, this Prins cyclization was found to proceed well only at room temperature with a stoichiometric amount of InCl₃ as promoter in CH₂Cl₂; 5) our desired cyclization product 2,6-cis-dihydropyran was obtained as a major diastereoisomer in low yields with the concurrent formation of the 2,6-trans-dihydropyran isomer with a moderate diastereoselectivity of ~ 75 : 25 (cis/trans). Details and results of the screening of reaction conditions are summarized in Table 5.5. Results of Prins cyclization of 109 with various aldehydes are tabulated in Table 5.6.

<sup>a</sup>Acetyl allenic alcohol 109 (0.3 mmol, in 1mL CH₂Cl₂) was introduced via syringe pump over 3 hours into the vigorously stirred suspension of a mixture of InCl₃ (0.3 mmol) with TMSCl (0.45 mmol) and the corresponding aldehyde (0.45 mmol) in 5 mL CH₂Cl₂ at 25 °C, stirred for another 2 hours after finishing introducing 109, followed by aqueous workup and purification. <sup>b</sup>combined yield. <sup>c</sup>Determined by <sup>1</sup>H nmr spectrum. <sup>d</sup>N.R. denotes no reaction with the recovery of starting materials.
We could see that our strategy did afford us with the desired 2,6-cis-disubstituted-3-methyl-4-chloro-dihydropyans as the major product (Table 5.5). However, the overall yields were quite low and the cis/trans diastereoselectivity was moderate. Undesired side reactions may probably contribute to the low yield problem during this Prins cyclization, including dimerization, polymerization and decomposition of the starting allenic alcohol. The exact reasons were not established, however, our experimental observations indicated low stability of the acetyl allenic alcohol under the harsh acidic conditions in Prins cyclization, and the volatility, low stability of dihydropyran products during isolation and purification. Obviously, further efforts are necessary to solve all these problems.

The formation of 2,6-trans-dihydropyrans was believed to be of the same mechanism, originating from the directing stereoelectronic interaction between the lone pair on carbonyl oxygen and the positive-charged oxocarbenium carbon during the cyclization.

5.3 **SYNTHETIC STUDIES TOWARDS (+)-SAMBUTOXIN**

5.3.1 Introduction to (+)-Sambutoxin

(+)-Sambutoxin is an interesting mycotoxin isolated by Lee and co-workers in 1995 from the wheat cultures of *Fusarium sambucinum* PZF-4. This metabolite is structurally representative of a small class of natural products, featured with its central 2,6-cis-tetrahydropyran ring backbone linked with the 4-hydroxy-2-pyridinone motif

---

and the 1,3-anti-dimethyl tail, examples including funiculosin\textsuperscript{17} and oxysporidinone\textsuperscript{18} (Figure 5.2). These toxins exhibit a broad spectrum of biological activities including antibiotic, antiinsecticidal, antifugal, and antitumor properties. These structural features with their interesting biological activities aroused our strong interest to carry our synthetic studies towards these natural products.

![Figure 5.2 Natural products containing THP (DHP) ring backbone and pyridinone moiety.](image)

5.3.2 Reported Synthesis of (+)-Sambutoxin

The first enantioselective total synthesis of (+)-Sambutoxin was reported by Williams, D.R. in 2000.\textsuperscript{19} It is the first and the only completed total synthesis of this metabolite by far (Scheme 5.10), and this total synthesis featured four key operations: 1) an enantioenriched preparation of 1,3-anti-dimethyl array by asymmetric conjugate addition of Yamamoto’s copper reagents onto the conjugate ketone with Hruby’s 4-phenyloxazolidinone auxiliary \textsuperscript{20} to establish the intermediate I. Excellent diastereofacial selectivity was observed due to a double induction stemming from the asymmetry of the homochiral copper species possessing a syn-s-cis chelation manner.

as depicted in the transition state; 2) Paterson anti-Aldol reaction\textsuperscript{21} to afford compound II with E-(O)-boron enolate, which was generated \textit{in situ} by reacting the chiral ketone (derived from (S)-ethyl lactate) with boron-based chiral auxiliary \textsuperscript{2}He\textsubscript{2}BCl. II was obtained in 78\% yield as a single, crystalline diastereomer, and the complete stereocontrol was believed to be achieved \textit{via} a boat-like transition state without a substantial barrier in energy based on theoretical calculations. Further elaborations transformed II into III by sequential standard chemical transformations, such as silyl ether formation, oxidative cleavage of the chiral auxiliary, and homologation of the carbon chain, and coupling condensation of III with the protected amino aldehyde yielded the precursor IV for construction of pyridinone; 3) the key intermediate pyridinone V was formed \textit{via} an oxidative cyclization cascade from enol ether IV when treated with DBU and bromotrichloromethane;\textsuperscript{22} 4) after removal of the TBS sily ether from V with TBAF, the formation of the central skeletal backbone of (+)-Sambutoxin VII was finished with the exclusive formation of the tetrahydropyran ring showing a 2,6-\textit{cis}-diequatorial substitution pattern through a novel Saegusa oxidation cyclization cascade sequence mediated by palladium acetate \textit{via} formation of the pridinone methide VI with a subsequent intramolecular conjugate addition.\textsuperscript{23} Hydrolytic deprotection of the β–methoxymethyl ether afforded (+)-Sambutoxin, which was confirmed as the antipode of the natural product with identical nmr parameters but opposite optical rotational angle.

5.3.3 Retrosynthetic analysis of (+)-Sambutoxin

In our opinion, the structural features of (+)-Sambutoxin come from its tetrahydropyran ring backbone and its 1,3-anti-dimethyl tail linked by a double bond. Based on our knowledge in Prins cyclization\(^6\) and copper-tol-BINAP complex
catalyzed asymmetric conjugate addition,\textsuperscript{24} a facile and straightforward retro-synthetic analysis was proposed, as depicted in Scheme 5.11. The skeleton of (+)-Sambutoxin was disconnected into VIII and fragment C upon a retro-Julia olefination reaction.\textsuperscript{25} Fragment C was envisioned to be readily prepared through an iterative asymmetric 1,4-conjugate addition reaction using Cu-tol-BINAP catalyst to generate the 1,3-\textit{anti}-dimethyl array.\textsuperscript{24b} The precursor VIII could be derived from IX via a radical dehalogenation\textsuperscript{26} and a subsequent stereoselective hydrogenation process.\textsuperscript{27} A retro-Prins cyclization further cut IX into the protected pyridinone aldehyde A and acetyl allenic alchol B. Fragment A could be prepared \textit{via} condensation of phenylacetonitrile with dimalonyl chloride\textsuperscript{28} followed with incorporation of the aldehydic function,\textsuperscript{29} and B could be readily obtained by allenation of the ketone-aldehyde.\textsuperscript{30} In general, our synthetic strategy towards (+)-Sambutoxin could be highlighted as three key operations, including Prins cyclization, asymmetric conjugate addition and Julia olefination reaction.

\textsuperscript{27} For a stereoselective hydrogenation of the dihydropyran to tetrahydropyran with methyl residing on equatorial position see: Nawata, Y.; Matsuura, I.; Ando, K.; Iitaka, Y. \textit{Acta. Cryst.} \textbf{1990}, \textit{C46}, 515.

5.3.4 Synthesis of Fragment A

As described in the retro-synthetic analysis, we started our synthetic study towards (+)-Sambutoxin by focusing our initial efforts on the key Prins cyclization step to form the skeletal tetrahydropyran backbone. The key precursor, fragment A for this Prins cyclization, was prepared over three steps by following literature reported methods (Scheme 5.12). Condensation of p-methoxyphenyl acetonitrile with malonyl
PRINS CYCLIZATION OF ALLENIC ALCOHOLS AND SYNTHETIC STUDY TOWARDS (+)-SAMBUTOXIN

chloride afforded 44% of chloropyridinone 126, where the black slurry-like reaction crude needs careful and tedious purification.\textsuperscript{28} Double methylation product 127 was obtained in one step \textit{via} methylation with dimethyl sulfate in the presence of aqueous sodium hydroxide.\textsuperscript{28} Deprotonation of vinylic proton of 127 upon treatment with \textit{n}-BuLi at -78 °C followed by reaction with DMF provided desired pyridinone aldehyde \textit{A} in 71% yield.\textsuperscript{28} In addition, the structures of 127 and fragment \textit{A} could be readily seen from their respective X-ray single crystal structures (Figure 5.3 and Figure 5.4).

![Scheme 5.16 Synthesis of fragment A, chloropyridinone aldehyde.](image)

Figure 5.3 X-ray structure of 127.  Figure 5.4 X-ray structure of fragment A.

5.3.5 Prins cyclization of pyridinone aldehyde (Fragment A) with acetyl allenic alcohol (Fragment B)

With the starting fragments \textit{A} and racemic \textit{B} (109) available in hand, we proceeded to carry out the key step of our strategy, the Prins cyclization reaction between fragment \textit{A} and 109. Unfortunately, no cyclization product could be observed when pyridinone aldehyde \textit{A} was subjected to the optimal cyclization
conditions described above (Table 5.7, entry 1). We also attempted other cyclization conditions by using different Lewis acids and counterion additive, however, no desired product was formed in spite of our efforts (Table 5.7, entries 2 to 4). We suspect that the low reactivity might arise from the pyridinone aldehyde $A$ because of its conjugate nature. Thus, we turned to the versatile catalyst $(\text{O}_3\text{ReOSiPh}_3)_3$, which is especially reactive for promoting Prins cyclization with aromatic and conjugate aldehydes. However, it also failed to afford our desired cyclized dihydropyran backbone (Table 5.7, entries 5 to 7). Thus, it turns out that our Prins cyclization fails to work as the key strategy to generate the backbone of (+)-Sambutoxin and we temporarily ceased our synthesis at this stage. Further efforts are necessary with a new generation of Prins cyclization strategy for facile and rapid assembly of the backbone of this interesting mycotoxin.

Table 5.7 Synthesis of key precursor $\text{IX}$ via Prins cyclization of $A$ with $109$.

$^a$ N.R. denotes no reaction occurred with starting material recovered. $^b$ Starting allenic alcohol decomposed, pyridinone aldehyde recovered.

5.4 CONCLUSION

In conclusion, a novel cis Prins cyclization reaction of common allenic alcohols with aldehydes has been developed via suppression of undesirable oxonia-Cope rearrangement. At reduced reaction temperature and concentration, Prins cyclization of TMS-substituted allenic alcohol proceeds smoothly catalyzed by the mild Lewis acid indium trifluoroacetate with excellent chemical yields and stereoselectivity. While, it was a bit more complicated for Me-substituted allenic alcohols, the desired DHP products could only be formed by incorporating a carbonyl function adjacent to the hydroxyallenyl moiety so as to suppress the oxonia-Cope rearrangement, where the overall chemical yields were low with moderate stereoselectivities observed. The application of this methodology to the synthesis of (+)-Sambutoxin was unsuccessful due to the low reactivity of the starting pyridinone aldehyde.
CHAPTER 6

Experimental Section
6.1 GENERAL METHODS

Moisture and/or sensitive reactions were performed under a positive pressure of nitrogen in flame-dried glassware equipped with a rubber septum inlet. Solvents and liquid reagents were transferred by oven-dried syringes cooled in a dessicator or via double-tipped cannular needles. Reaction mixtures were stirred with Teflon-coated magnetic stirring bars unless otherwise stated. Moisture in non-volatile reagents/compounds was removed by the addition of the stated amount of anhydrous THF, followed by the removal of the solvent and traces of moisture in vacuo by means of an oil pump and subsequent purging with nitrogen.

All experiments were monitored by analytical thin layer chromatography.

Solvents were removed in vacuo under ~30 mmHg and heated with a water bath at 23 °C using Büchi rotary evaporator cooled with circulating ethylene glycol/water mixture (1:1) at -5 °C.

Materials

Reagents were purified prior to use unless otherwise stated following the guidelines of Perrin and Armarego. Solvents such as hexane, ethyl acetate, dichloromethane and water were freshly distilled prior to use. Anhydrous THF was obtained by distillation under nitrogen atmosphere from a deep purple solution resulting from sodium and benzophenone. Anhydrous dichloromethane was distilled over calcium hydride under nitrogen atmosphere. Azeotropic drying of starting materials or reagents was performed by the addition of the stated amount of anhydrous tetrahydrofuran, ensued by azeotropic removal of tetrahydrofuran with traces of moisture in vacuo followed by subsequent purging with nitrogen.

Triethylamine, toluene and dimethyl sulfoxide were distilled over calcium hydride and stored over molecular sieves to maintain dryness. DMF was distilled over Linde type 4A molecular sieve prior to usage. 1N hydrochloric acid was diluted from concentrated 37% solution using deionised water. 1M sodium hydroxide solution was prepared from sodium hydroxide pearls. Saturated solutions of ammonium chloride, sodium chloride, sodium bicarbonate, and sodium carbonate were prepared from their respective solids.

**Chromatography**

Analytical thin layer chromatography was performed using Merck 60 F$_{254}$ pre-coated silica gel plates (0.25 mm thickness). Visualization was accomplished with UV light (254 nm) and potassium permanganate solution or ceric molybdate solution followed by heating on a hot plate.

Flash column chromatography was performed using Merck Silica Gel 60 (0.010-0.063 nm) and freshly distilled solvents. Columns were packed as slurry of silica gel in hexane and equilibrated with the appropriate solvent/solvent mixture prior to use. The solute was loaded neat or as a concentrated solution using the appropriate solvent system. The elution was assisted by applying pressure with an air pump.

**Instruments & Equipments**

Infrared Spectroscopy

Infrared spectra were recorded on a Shimadzu IR Prestige-21 FT-IR Spectrometer. Solid samples were analyzed as a KBr pressed-disk while liquid samples were either examined neat between KBr or NaCl salt plates or as a solution in dichloromethane using NaCl liquid cells.
Mass Spectroscopy

Mass spectrometry was performed by the staffs in the Division of Chemistry and Biological Chemistry of the Nanyang Technological University. MS (EI) spectra were recorded on a Thermo Finnigan Polaris Q GCMS. MS (ESI and APCI) spectra were recorded on a Thermo Finnigan LCQ Deca XP Max. HRMS (EI, ESI, FAB) spectra were recorded on a Thermo Finnigan MAT 95 XP. MS and HRMS were reported in units of mass of charge ratio (m/z).

Nuclear Magnetic Resonance Spectroscopy

Proton nuclear magnetic resonance (\(^1\)H NMR) and carbon nuclear magnetic resonance (\(^{13}\)C NMR) spectroscopy were performed on a Bruker Avance 300, 400 and 500 NMR spectrometers. Chemical shifts were reported as \(\delta\) in units of parts per million (ppm) downfield from tetramethylsilane (\(\delta\) 0.00), using the residual solvent signal as an internal standard: deuterio chloroform-\(d\), CDCl\(_3\) (\(^1\)H NMR, \(\delta\) 7.26, singlet; \(^{13}\)C NMR, \(\delta\) 77.03, triplet). Multiplicities were given as: s (singlet), d (doublet), t (triplet), q (quartet), quint (quintet), m (multiplets), br (broad), dd (doublet of doublets), dt (doublet of triplets), ddd (doublet of doublet of doublets) and ddt (doublet of doublet of triplets). Coupling constants (\(J\)) were recorded in Hertz (Hz). The number of protons (n) for a given resonance was indicated by nH.

Nomenclature

Systematic nomenclature for the compounds would follow the numbering system as defined by IUPAC. Compounds were named with assistance from CS Chemdraw Ultra 9.0 software.
6.2 **TRANS PRINS CYCLIZATION**

**PROCEDURES AND DATA**

**Preparation of (Z)-γ-brominated-homoallylic alcohol.**

1. To an oven dried (50 mL) round-bottom flask equipped with a magnetic stirring bar was added diisopropylamine (10.0 mmol, 1.40 mL), and anhydrous tetrahydrofuran (10 mL). The mixture was cooled to 0 °C prior to dropwise addition of *n*-butyl lithium (10.0 mmol, 6.3 mL, 1.6 M in hexane). The mixture was stirred at 0 °C for 30 minutes before being transferred into the other flask.

2. To an oven dried (100 mL) round-bottom flask equipped with a magnetic stirring bar was added ZnBr₂ (2.5 mmol, 0.5630 g, 1.25 equiv.), allyl bromide (5.0 mmol, 0.43 mL, 2.5 equiv.) and tetrahydrofuran (20 mL). The mixture was stirred and cooled to -78 °C. The preformed LDA was added dropwise via a plastic cannula and the mixture was stirred for around 20 minutes. Hydrocinnamaldehyde (2.0 mmol, 0.26 mL, 1.0 equiv.) was then added. Reaction was allowed to proceed for 3 hours at -78 °C. The reaction was quenched by pouring the reaction mixture into 1 M HCl solution (20 mL). The aqueous layer was extracted with diethyl ether (50 mL × 3) and the combined organic extracts were washed with water and brine, and dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo*. The residual crude product was purified via flash chromatography (10% diethyl ether in hexane) to afford 4-bromo-1-phenylhex-5-en-3-ol (1) in 37% yield and (Z)-6-bromo-1-phenyl-hex-5-en-3-ol (4) as a pale yellow oil in 62 % yield.

**Procedures for Prins cyclization of syn and anti bromohydrin with aldehyde**

To an oven-dried (25mL) round-bottom flask equipped with a magnetic stirring bar was added indium triflate (67.4 mg, 0.12 mmol, 0.20 equiv.) and anhydrous dichloromethane (6 mL). The mixture was allowed to cool to 0 \(^\circ\)C with vigorous stirring. 4-Bromo-1-phenylhex-5-en-3-ol (1) (154.8 mg, 0.60 mmol, 1.0 equiv.) in 1 mL dry CH\(_2\)Cl\(_2\) was introduced into the suspension, and 5 minutes later bromotrimethylsilane (TMSBr, 0.12 mL, 0.90 mmol, 1.5 equiv.) was added. Hydrocinnamaldehyde (80.5 mg, 0.60 mmol, 1.0 equiv.) in 1 mL dry CH\(_2\)Cl\(_2\) was slowly introduced over 10 minutes. The reaction was allowed to proceed at 0 \(^\circ\)C for 3 hours before quenching with saturated sodium bicarbonate solution (5 mL). The aqueous layer was extracted with dichloromethane (10 mL \(\times\) 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo*. The residual crude product was purified *via* flash chromatography (0.5% diethyl ether in hexane) to afford 3,4-dibromo-2,6-diphenethyl-tetrahydro-2H-pyran (2) and (3) in 47% and 16% yield, respectively.

\[(Z)-1\text{-phenyl-6-trimethylsilanyl-hex-5-en-3-ol} \]
To an oven dried (50 mL) round-bottom flask equipped with a magnetic stirring bar was added 1-phenyl-6-trimethylsilanyl-hex-5-yn-3-ol (1.0 mmol, 246.4 mg, 1.0 equiv.) diluted with 1.5 mL anhydrous diethyl ether and stirred at 0 °C. DIBAL-H in heptane (1.0M in heptane, 2.6 mL, 2.6 mmol, 2.6 equiv.) was slowly added. The reaction was allowed to proceed at room temperature for 29 hours before quenching with methanol (10 mL) and saturated sodium potassium tartrate solution (10 mL). The aqueous layer was extracted with diethyl ether (20 mL × 3) and the combined organic extracts were washed with water and brine, and dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (5.0 % ethyl acetate in hexane) to afford the (Z)-1-phenyl-6-trimethylsilyl-hex-5-en-3-ol as a colorless oil in 64 % yield.

Rf: 0.47 (hexane : ethyl acetate = 4 : 1), yield: 64%.

1H NMR (400 MHz, CDCl3) δ 7.30-7.17 (m, 5H), 6.32 (ddd, J = 7.00, 7.96, 14.32 Hz, 1H), 5.70 (td, J = 1.16, 14.12 Hz, 1H) 3.70-3.67 (m, 1H), 2.82-2.73 (m, 1H), 2.71-2.67 (m, 1H), 2.36-2.30 (m, 1H), 1.83-1.77 (m, 1H), 1.57 (d, J = 4.00 Hz, 1H), 0.13 (s, 9H).

(E)-6-bromo-1-phenylhex-5-en-3-ol (11)
To an oven dried (50 mL) round-bottom flask equipped with a magnetic stirring bar was added \((Z)-1\)-phenyl-6-trimethylsilyl-hex-5-en-3-ol (1126.9 mg, 5.11 mmol, 1.0 equiv.) diluted with 15 mL anhydrous dichloromethane, and cooled to -78 °C with stirring. Bromine (0.26 mL, 5.11 mmol, 1.0 equiv.) was added dropwise into the solution of \((Z)-1\)-phenyl-6-trimethylsilyl-hex-5-en-3-ol. The reaction was quenched by adding 10% Na₂SO₃ solution upon the persistence of brownish color. Reaction mixture was extracted with dichloromethane (50 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous sodium sulfate, and filtered. The filtrate was cooled to -20 °C prior to addition of TBAF (10.22 mL, 10.22 mmol, 2.0 equiv.). The mixture was allowed to be stirred at -20 °C for 30 minutes. The reaction mixture was concentrated in vacuo. The residual crude was purified via flash chromatography (20% ethyl acetate in hexane) to afford \((E)-\gamma\)-brominated-homoallylic alcohol as a yellow oil in 90% yield.

**Rf:** 0.34 (hexane : ethyl acetate = 4 : 1), yield: 90%.

**¹H NMR** (400 MHz, CDCl₃) δ 7.30-7.18 (m, 5H), 6.20 (td, \(J = 7.36, 13.60\) Hz, 1H), 6.12 (d, \(J = 13.60\) Hz ) 3.68-3.65 (m, 1H), 2.79 (td, \(J = 8.12, 13.39\) Hz, 1H), 2.66 (td, \(J = 8.26, 13.96\) Hz,1H), 2.29-2.22 (m, 1H), 2.17 (td, \(J = 7.49, 14.13\) Hz, 1H), 1.79-1.73 (m, 3H).

**General Procedures for the construction of 2,6-cis-dibromo-tetrasubstituted tetrahydropyrans.**

To an oven-dried (25 mL) round-bottom flask equipped with a magnetic stirring bar was added indium bromide (106.0 mg, 0.30 mmol, 1.0 equiv.) and anhydrous dichloromethane (1.5 mL). The mixture was allowed to cool to 0 °C with vigorous stirring. (Z)-γ-Brominated-homoallylic alcohol (91.8 mg, 0.36 mmol, 1.2 equiv.) in 1 mL dry CH$_2$Cl$_2$ was introduced into the suspension, and 5 minutes later bromotrimethylsilane (TMSBr, 0.05 mL, 0.36 mmol, 1.2 equiv.) was added. Cyclohexanecarboxaldehyde (33.7 mg, 0.30 mmol, 1.0 equiv.) in 1 mL dry CH$_2$Cl$_2$ was slowly introduced over 10 minutes. The reaction was allowed to proceed at 0 °C for 90 minutes before quenching with saturated sodium bicarbonate solution (5 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane) to afford 5 as a white solid in 95 % yield.

Procedures of debromination of 2,6-cis-4,5-dibromo-tetrahydropyran.

Approach 1. To an oven-dried (25 mL) round-bottom flask equipped with a magnetic stirring bar was added 5 (44.9 mg, 0.10 mmol, 1.0 equiv.) in 2.5 mL anhydrous glacial acetic acid and activated zinc (68.8 mg, 1.0 mmol, 10.0 equiv.). The reaction was allowed to proceed at room temperature for 24 hrs before diluting with diethyl ether (10 mL). The combined organic extracts were washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.4% diethyl ether in hexane) to afford 18 as a pale yellow oil in 70% yield.
Approach 2. To an oven dried 25 mL round-bottom flask equipped with a magnetic stirring bar was added 5 (24.5 mg, 0.06 mmol, 1.0 equiv.) and tributyltin hydride (0.015 mL, 0.06 mmol, 1.0 equiv.) in 1 mL anhydrous toluene and ACCN (1,1’-azobis(cyclohexane) carbonitrile, 1.2 mg, 0.005 mmol, 0.10 equiv.). The reaction was allowed to proceed at 110 °C for 24 hrs before quenching with saturated KF solution (15 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (1% diethylether in hexane) to afford (2S*,6R*)-6-cyclohexyl-2-phenethyl-3,6-dihydro-2H-pyran 18 as a pale yellow oil in 71% yield.

Procedures of elimination of 2,6-cis-4,5-dibromo-tetrahydropyran (5)
To an oven-dried 10 mL round-bottom flask equipped with a magnetic stirring bar was added 5 (136.3 mg, 0.32 mmol, 1.0 equiv.) in 1 mL dry ethanol and potassium tert-butoxide (0.64 mL, 0.64 mmol, 2.0 equiv.). The reaction was allowed to proceed at room temperature for 24 hrs before quenching with saturated ammonium chloride solution (5 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extract was washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.4% diethyl ether in hexane) to afford (2S*,6R*)-4-bromo-6-cyclohexyl-2-phenethyl-3,6-dihydro-2H-pyran (19) as a colorless oil in 69% yield.

Procedures of elimination of 2,6-cis-4,5-dibromo-tetrahydropyran (12)

To an oven-dried 10 mL round-bottom flask equipped with a magnetic stirring bar was added 12 (86.0 mg, 0.20 mmol, 1.0 equiv.) in 2 mL dry α,α,α-trifluorotoluene and potassium tert-butoxide (0.40 mL, 0.40 mmol, 2.0 equiv.). The reaction was allowed to proceed at refluxing temperature (~110 °C) for 24 hrs before quenching with saturated ammonium chloride solution (5 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extract was washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.4% diethyl ether in hexane) to afford (2S*,6R*)-4-bromo-6-cyclohexyl-2-phenethyl-3,6-dihydro-2H-pyran (19) as a colorless oil in 59% yield.

**General Procedure for trans Prins Cyclization of carboalkoxy Allenic Alcohols**

**Preparations of n-butyl glyoxylate**

To a solution of di-n-butyl tartrate (2.62 g, 10 mmol) in dry ether (60 mL) cooled was added periodic acid (2.28 g, 10 mmol) in portions over 1 h under N₂ at 0 °C. The resulting reaction was stirred for 4 h, decanted from the solid precipitate, dried over Na₂SO₄, filtered, and concentrated in vacuo. The residue was distilled under reduced pressure to give n-butyl glyoxylate (2.45 g) as a viscous oil in 94% yield; b. p. 55-63 °C/12 mmHg.

**Preparation of butyl 2-hydroxy-3-methylpenta-3,4-dienoate (20)**
1-Bromo-2-butyne (1.33 g, 10 mmol, 2.0 equiv) was added to a mixture of \textit{n}-butyl glyoxylate (0.65 g, 5 mmol, 1.0 equiv) and indium powder (1.15 g, 10 mmol, 2.0 equiv) in THF/NH₄Cl(aq. sat.) (1:5, 20 mL) at 0 °C with vigorous stirring. After 0.5 hour, the mixture was warmed to room temperature and kept for another 6 hours, and finally quenched with 20 mL of 1 M HCl solution. The aqueous layer was extracted with ethyl acetate (30 mL \times 3). The combined organic extracts were washed with brine, dried over anhydrous MgSO₄, concentrated under vacuum, and purified by flash gel column chromatography to provide 20 in 83% yield as a clear oil.

To an oven dried 10 mL round-bottom flask with a magnetic stirring bar was added indium(III) triflate (16.9 mg, 0.03 mmol, 0.1 equiv) in 2 mL anhydrous CH₂Cl₂. The mixture was allowed to cool to 0 °C prior to addition of trimethylsilylbromide (55.1 mg, 0.36 mmol, 1.2 equiv). Cyclohexanecarboxaldehyde (40.4 mg, 0.36 mmol, 1.2 equiv) was added within 5 minutes. Then a solution of butyl 2-hydroxy-3-methylpentad-3,4-dienoate (20, 55.3 mg, 0.3 mmol, 1.0 equiv) dissolved in 1 mL anhydrous CH₂Cl₂ was added using syringe pump addition over a period of 1 hour. The reaction was stirred at 0 °C for 2 hours, warming up to room temperature. The
mixture was quenched with saturated NaHCO$_3$ aqueous solution (10 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3). The combined organic layers were washed with water, brine, and dried over anhydrous MgSO$_4$, filtered and concentrated in vacuo. The residue crude product was purified by flash column chromatography to afford dihydropyran-2-ols in 84% yield and 21' in 12% yield as colorless oil.

6.3 FCP CASCADE CONDESATION OF PROARGYLIC EPOXIDES

**PROCEDURES AND DATA**
Preparation of 1-Phenyl-6-trimethylsilanyl-hex-5-yn-3-ol (34)

Trimethylsilylpropargyl bromide (956 mg, 5.0 mmol, 1.25 equiv.) was added to a suspension of the indium powder (574 mg, 5.0 mmol, 1.25 equiv.) and indium bromide (142 mg, 0.40 mmol, 0.1 equiv.) in 5 mL anhydrous THF at room temperature. After 15 minutes, hydrocinnamaldehyde (537 mg, 4.0 mmol, 1.0 equiv.) was added at room temperature. The mixture was refluxed overnight, and quenched with 50 mL 1M HCl solution. The aqueous layer was extracted with diethyl ether (50 mL × 3), and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, concentrated in vacuo, and purified via flash chromatography (20% ethyl acetate in hexane) to afford 1-phenyl-6-trimethylsilanyl-hex-5-yn-3-ol in 60% yield as a yellow oil.

Preparation of 1-phenyl-6-(trimethylsilyl)hex-5-yn-3-yl benzoate (35)

To an oven dried (10 mL) round-bottom flask equipped with a magnetic stirring bar was added with 1-phenyl-6-trimethylsilanyl-hex-5-yn-3-ol (34) (0.5 mmol, 123.2 mg, 1.0 equiv.), DMAP (0.05 mmol, 6.1 mg, 0.1 equiv.) and triethylamine (1.5 mmol, 0.21 mL, 3.0 equiv.), diluted with 3 mL anhydrous dichloromethane and stirred at 0 °C. Benzoyl chloride (0.15 mL, 0.6 mmol, 1.2 equiv.) was slowly added. The reaction was allowed to warm up to room temperature and stirred for overnight before quenching saturated sodium bicarbonate solution (10 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with water and brine, and dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (1% diethyl ether in hexane) to afford the 1-phenyl-6-(trimethylsilyl)hex-5-yn-3-yl benzoate 35 in 96 % yield as a colorless oil.

Preparation of (Z)-trimethyl(6-phenylhex-3-en-1-ynyl)silane (36)

1. To an oven dried (25 mL) round-bottom flask equipped with a magnetic stirring bar was added diisopropylamine (1.10 mmol, 0.15 mL, 2.0 equiv.), and anhydrous THF (5 mL). The mixture was cooled to 0 °C prior to dropwise addition of n-butyl lithium (1.6 M in hexane) (1.10 mmol, 0.68 mL, 2.0 equiv.). The mixture was stirred at 0 °C for 30 minutes before being transferred into the target flask.

2. To an oven dried 25 mL round-bottom flask equipped with a magnetic stirring bar was added 1-phenyl-6-(trimethylsilyl)hex-5-yn-3-yl benzoate (35, 1.839 g, 0.52 mmol, 1.0 equiv.) and TIPSCl (1.10 mmol, 0.23 mL, 2.0 equiv.) and was diluted with 5 mL anhydrous THF, stirred and cooled to around -93 °C (low temperature was generated by using toluene and liquid nitrogen). The preformed LDA was transferred via a plastic cannula in a dropwise manner into the solution of 35. The reaction was allowed to proceed at -93 °C for 3 hours. The reaction was quenched by pouring the reaction mixture into 1 M HCl solution (10 mL). The reaction mixture was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous sodium sulfate, filtered. The reaction mixture was concentrated in vacuo. The residual crude was purified via flash chromatography (0.2 % diethyl ether in hexane) to afford 36 and 37 (Z/E = 90:10) in an overall 77 % yield as a colorless oil.

**General procedures for preparing polycyclic furans via indium triflate-mediated Friedel-Crafts-Prins cascade condensation of cis propargylic epoxide with aldehydes**

To an oven-dried (10 mL) round-bottom flask equipped with a magnetic stirring bar was added indium triflate (56.2 mg, 0.1 mmol, 1.0 equiv.) and anhydrous dichloromethane (1 mL), vigorously stirred at room temperature. Propargylic epoxide
40 (17.2 mg, 0.1 mmol, 1 equiv., dissolved in 1 mL dry CH$_2$Cl$_2$) was introduced into the suspension, stirred at room temperature for 1 hour. Bromotrimethylsilane (TMSBr, 0.03 mL, 0.20 mmol, 2 equiv.) was added. Cyclohexanecarboxaldehyde (11.2 mg, 0.1 mmol, 1.0 equiv.) in 1 mL dry CH$_2$Cl$_2$ was introduced in a dropwise manner. The reaction was allowed to proceed at room temperature for 2 hours before quenching with saturated NaHCO$_3$ solution. The aqueous layer was extracted with dichloromethane (10 mL \times 3). The combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated \textit{in vacuo}. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane 0.5%) to afford 44 in 81 \% yield as a colorless oil.

**EXPERIMENTAL SECTION**

**General procedures for preparing polycyclic furans via crossed [3+3] type annulation**

![Chemical Structure](image)

To an oven-dried (10 mL) round-bottom flask equipped with a magnetic stirring bar was added trifluoroborate etherate (0.013 mL, 0.10 mmol, 1.0 equiv) and anhydrous dichloromethane (1 mL), vigorously stirred at room temperature. Propargylic epoxide 40 (17.2 mg, 0.1 mmol, 1.0 equiv, dissolved in 1 mL dry CH₂Cl₂) was introduced into the suspension, and stirred at room temperature for 1 hour. Furan 48 (25.4 mg, 0.10 mmol, 1.0 equiv., in 1 mL CH₂Cl₂) was added. Nonyl aldehyde (14.2 mg, 0.1 mmol, 1.0 equiv, dissolved in 1 mL dry CH₂Cl₂) was introduced slowly over 15 minutes. The reaction was allowed to proceed at room temperature for 3 hours before quenching with saturated NaHCO₃ solution. The aqueous layer was extracted with dichloromethane (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo*. The residual crude product was purified via flash chromatography (0.3% diethyl ether in hexane) to afford 57 as a colorless oil in 47% yield.

**Procedures for preparing polycyclic pyrans via indium triflate-catalyzed Friedel-Crafts-Prins cascade condensation of trans Propargylic epoxide with aldehydes**
To an oven-dried 10 mL round-bottom flask equipped with a magnetic stirring bar was added indium triflate (11.2 mg, 0.02 mmol, 0.2 equiv.) and anhydrous dichloromethane (1.5 mL). The mixture was cooled to 0 °C with vigorous stirring. Propargylic epoxide 41 (17.2 mg, 0.1 mmol, 1.0 equiv. dissolved in 1 mL dry CH₂Cl₂) was introduced into the suspension, stirred at 0 °C for 4 hour, then cooled to -20 °C. Bromotrimethylsilane (TMSBr, 0.016 mL, 0.12 mmol, 1.2 equiv.) was added. Cyclohexanecarboxaldehyde (11.2 mg, 0.1 mmol, 1.0 equiv. dissolved in 1.0 mL dry CH₂Cl₂) was introduced in a dropwise manner. The reaction was allowed to proceed at -20 °C for 6 hours before quenching with saturated sodium bicarbonate solution (3 mL). The aqueous layer was extracted with diethyl ether (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane) to afford 62 in 87 % yield.

### 6.4 FCP CASCADE CONDESATION OF ALynyL EPOXIDES

**PROCEDURE AND DATA**

**General procedures for preparation of Allylic Epoxide 72 and 73**

To an oven-dried 100 mL round-bottom flask equipped with a magnetic stirring bar was added 40 (411.8 mg, 2.39 mmol, 1.0 equiv.) and Lindlar catalyst (palladium on CaCO$_3$ poisoned with 3.5% Pb, 50.9 mg, 0.48 mmol, 0.20 equiv.). The mixture was diluted with 30 mL ethyl acetate, vigorously stirred at -20 $^\circ$C under the atmosphere of hydrogen gas. Reaction was allowed to proceed at -20 $^\circ$C for 2.5 hours before quenching with saturated NaHCO$_3$ solution (5 mL). The aqueous layer was extracted with diethyl ether (10 mL $\times$ 3) and the combined organic extract was washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated *in vacuo*. The residual crude product was purified *via* flash chromatography (1% diethyl ether in hexane) to afford 72 in 96% yield as a colorless oil.

General procedures for preparing polycyclic tetrahydropyrans via indium triflate-mediated Friedel-Crafts-Prins cascade condensation of cis allylic epoxide with aldehydes

To an oven-dried (10 mL) round-bottom flask equipped with a magnetic stirring bar was added indium triflate (11.2 mg, 0.020 mmol, 0.20 equiv) and anhydrous dichloromethane (1 mL). The mixture was vigorous stirred at 0 °C. Allylic epoxide 40 (17.2 mg, 0.1 mmol, 1.0 equiv, dissolved in 1 mL dry CH₂Cl₂) was introduced into the suspension, stirred at 0 °C for 2 hour. Bromotrimethylsilane (TMSBr, 0.016 mL, 0.12 mmol, 1.20 equiv) was added. Cyclohexanecarboxaldehyde (11.2 mg, 0.1 mmol, 1.0 equiv, dissolved in 1 mL dry CH₂Cl₂) was introduced in a dropwise manner. The reaction was allowed to proceed at 0 °C for 4 hours before quenching with saturated NaHCO₃ solution (3 mL). The aqueous layer was extracted with dichloromethane (10 mL × 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane) to afford 74 in 91 % yield.

6.5 **CIS PRINS CYCLIZATION OF ALLENIC ALCOHOLS**

**PROCEDURES AND DATA**

**Preparation of 1-phenyl-4-(trimethylsilyl)hexa-4,5-dien-3-ol (93)**

(3-Bromoprop-1-ynyl)trimethylsilane (0.85 mL, 6 mmol, 2.0 equiv) was added to a vigorous stirred mixture of hydrocinnamaldehyde (0.40 mL, 3.0 mmol, 1.0 equiv) and indium power (0.516 g, 4.5 mmol, 1.5 equiv) in THF/NH₄Cl(aq. sat.) (1:5, 18 mL) at 0 °C. Reaction was allowed to warm up to room temperature and proceed for around 12 hours before quenching with 10 mL of 1 M HCl solution. The aqueous layer was extracted with diethyl ether (20 mL × 3). The combined organic extracts were washed with brine, dried over anhydrous MgSO₄, concentrated under vacuum, and purified by flash chromatography (3% ethyl acetate in hexane) to afford 93 in 48% yield as a clear oil.

Rf: 0.5 (Hexane: diethyl ether = 4 : 1)

**1H NMR** (400 MHz, CDCl₃): 7.29 (m, 2H), 7.19 (m, 3H), 4.56 (m, 2H), 4.18 (s, 1H), 2.76 (m, 1H), 2.70 (m, 1H), 1.96 (m, 1H0, 1.84 (m, 1H), 1.66 (d, \(J = 5.98 \text{ Hz}, 1\)H), 0.14 (s, 9H)

General procedures for carrying out Prins cyclization using allenic alcohol 93 with various aldehydes at reduced reaction temperature and concentration

To an oven-dried 10 mL round-bottom flask equipped with a magnetic stirring bar was added indium trifluoroacetate (17.4 mg, 0.040 mmol, 0.20 equiv) and anhydrous dichloromethane (1 mL), stirred at -78 °C. Bromotrimethylsilane (TMSBr, 0.032 mL, 0.24 mmol, 1.20 equiv) was added, and followed with the introduction of cyclohexanecarboxaldehyde (22.4 mg, 0.2 mmol, 1.0 equiv, dissolved in 1 mL dry CH$_2$Cl$_2$). Allenic alcohol 93 (49.6 mg, 0.20 mmol, 1.0 equiv, dissolved in 1 mL dry CH$_2$Cl$_2$) was introduced into the suspension over around 10 minutes. The reaction was allowed to proceed at -78 °C for 18 hours before quenching with saturated NaHCO$_3$ solution (5 mL). The aqueous layer was extracted with dichloromethane (15 mL $\times$ 3) and the combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated in vacuo. The residual crude product was purified via flash chromatography (0.5% diethyl ether in hexane) to afford 94 in 81 % yield.

General procedures for carrying out Prins cyclization using allenic alcohol 109 with various aldehydes at room temperature

To an oven-dried 10 mL round-bottom flask equipped with a magnetic stirring bar was added indium trichloride (66.4 mg, 0.30 mmol, 1.0 equiv.) and anhydrous dichloromethane 4 mL, vigorously stirred at room temperature, followed with the introduction of 2-ethylbutylraldehyde (45.0 mg, 0.45 mmol, 1.50 equiv., dissolved in 1 mL dry CH\(_2\)Cl\(_2\) ) and TMSCl (0.60 mL, 0.45 mmol, 1.50 equiv.). Acetyl allenic alcohol 109 (39.8 mg, 0.30 mmol, 1.0 equiv. dissolved in 1 mL dry CH\(_2\)Cl\(_2\) ) was slowly introduced into the stirred mixture using syringe pump over 3 hours. After the addition of 109, reaction was allowed to proceed for another 2 hours at room temperature before quenching with saturated NaHCO\(_3\) solution. The crude was extracted with dichloromethane (15 mL x 3). Combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated \( \text{in vacuo} \). The residual crude product was purified \( \text{via} \) flash chromatography (0.3% diethyl ether in hexane) to afford 4-chloro-3-methyl-6-(pentan-3-yl)-5,6-dihydro-2\(H\)-pyran-2-yl)ethanone 110 and 111 in an overall 55% yield with a ratio (cis/trans) of 69:31.

**Procedures for preparing the 6-chloro-4-hydroxy-5-(4-methoxyphenyl)pyridin-2(1H)-one (126)**

To an oven-dried 50 mL round-bottom flask equipped with a magnetic stirring bar was added 4-methoxy-phenylacetonitrile (2.71 mL, 20 mmol, 1.0 equiv.). Freshly distilled malonyl chloride (7.0 mL, 36 mmol, 1.80 equiv.) was introduced in a dropwise manner. The mixture was stirred at room temperature for around 48 hours until slurry-like mixture was formed. Methanol (5 mL) was added dropwise to the mixture. The residual crude was then dissolved in saturated KOH solution (~ 10 mL), and was extracted with diethyl ether (10 mL x 3). The aqueous solution was acidified with concentrated HCl. The precipitate was filtered off under reduced pressure, and was washed with chloromethane (5 mL) and diethyl ether (5 mL). Solid was collected for chromatography (25% chloroform in methanol) to afford 6-chloro-4-hydroxy-5-(4-methoxyphenyl)pyridin-2(1H)-one 126 in 44 % yield as a pale yellow solid.

Appendix
Single crystal X-ray diffraction analysis of 5.

Empirical formula: $\text{C}_{19} \text{H}_{26} \text{Br}_2 \text{O}$

Formula weight: 430.22

Temperature: 273(2) K

Wavelength: 0.71073 Å

Crystal system: Monoclinic

Space group: $\text{P}2(1)/c$

Unit cell dimensions:
- $a = 10.4511(4)$ Å, $\alpha = 90^\circ$
- $b = 18.9558(7)$ Å, $\beta = 105.932(2)^\circ$
- $c = 9.7638(4)$ Å, $\gamma = 90^\circ$

Volume: 1860.00(12) Å$^3$

$Z$: 4

Density (calculated): 1.536 Mg/m$^3$

Absorption coefficient: 4.359 mm$^{-1}$

$F(000)$: 872

Crystal size: 0.40 x 0.20 x 0.20 mm$^3$

Theta range for data collection: 2.15 to 30.55°

Index ranges: $-14 \leq h \leq 14$, $-27 \leq k \leq 26$, $-13 \leq l \leq 13$

Reflections collected: 23668

Independent reflections: 5664 [R(int) = 0.0272]

Completeness to theta = 30.55°: 99.6 %

Absorption correction: Semi-empirical from equivalents

Max. and min. transmission: 0.4760 and 0.2745

Refinement method: Full-matrix least-squares on F$^2$

Data / restraints / parameters: 5664 / 0 / 303

Goodness-of-fit on F$^2$: 1.024

Final R indices [I>2sigma(I)]: $R_1 = 0.0264$, $wR_2 = 0.0553$

R indices (all data): $R_1 = 0.0426$, $wR_2 = 0.0599$

Largest diff. peak and hole: 0.541 and -0.335 e.Å$^{-3}$
Single crystal X-ray diffraction analysis of \(26\)

Single crystal X-ray diffraction analysis of 127

Empirical formula  C14 H14 Cl N O3
Formula weight  279.71
Temperature  173(2) K
Wavelength  0.71073 Å
Crystal system  Triclinic
Space group  P-1
Unit cell dimensions  
\[ a = 8.4398(2) \text{ Å} \]
\[ b = 11.7000(4) \text{ Å} \]
\[ c = 14.1294(4) \text{ Å} \]
\[ \alpha = 107.280(2)^\circ \]
\[ \beta = 101.179(2)^\circ \]
\[ \gamma = 95.394(2)^\circ \]
Volume  1289.74(6) Å³
Z  4
Density (calculated)  1.441 Mg/m³
Absorption coefficient  0.299 mm⁻¹
F(000)  584
Crystal size  0.34 x 0.30 x 0.26 mm³
Theta range for data collection  1.55 to 34.00°
Index ranges  -13<=h<=13, -18<=k<=18, -22<=l<=22
Reflections collected  47675
Independent reflections  10512 [R(int) = 0.0372]
Completeness to theta = 34.00°  99.8 %
Absorption correction  Semi-empirical from equivalents
Max. and min. transmission  0.9263 and 0.9051
Refinement method  Full-matrix least-squares on F²
Data / restraints / parameters  10512 / 0 / 349
Goodness-of-fit on F²  1.057
Final R indices [I>2sigma(I)]  
\[ R1 = 0.0470, wR2 = 0.1327 \]
R indices (all data)  
\[ R1 = 0.0707, wR2 = 0.1531 \]
Largest diff. peak and hole  0.964 and -0.626 e.Å⁻³
Single crystal X-ray diffraction analysis of A

Empirical formula C15 H14 Cl N O4
Formula weight 307.72
Temperature 173(2) K
Wavelength 0.71073 Å
Crystal system Triclinic
Space group P-1
Unit cell dimensions
\[ \begin{align*}
  a &= 6.5797(2) \text{ Å} & \alpha &= 78.6810(10)^\circ, \\
  b &= 9.4629(3) \text{ Å} & \beta &= 80.0220(10)^\circ, \\
  c &= 11.4678(3) \text{ Å} & \gamma &= 85.1050(10)^\circ.
\end{align*} \]
Volume 688.57(4) Å³
Z 2
Density (calculated) 1.484 Mg/m³
Absorption coefficient 0.293 mm⁻¹
F(000) 320
Crystal size 0.30 x 0.30 x 0.24 mm³
Theta range for data collection 1.83 to 25.50°.
Index ranges \(-7\leq h\leq 7, -11\leq k\leq 11, -13\leq l\leq 13\)
Reflections collected 11628
Independent reflections 2553 [R(int) = 0.0439]
Completeness to theta = 25.50° 99.4 %
Absorption correction Semi-empirical from equivalents
Max. and min. transmission 0.9330 and 0.9172
Refinement method Full-matrix least-squares on F²
Data / restraints / parameters 2553 / 0 / 192
Goodness-of-fit on F² 1.191
Final R indices [I>2sigma(I)] R1 = 0.0788, wR2 = 0.2356
R indices (all data) R1 = 0.0892, wR2 = 0.2624
Largest diff. peak and hole 0.690 and -0.556 e.Å⁻³
