Transition Metal-Catalyzed Functionalization of Alkynes and Arenes

BATHOJU CHANDRA CHARY

SCHOOL OF PHYSICAL AND MATHEMATICAL SCIENCES

A thesis submitted to the Nanyang Technological University
in partial fulfillment of the requirement for the degree of

Doctor of Philosophy

2013
I would like to dedicate this thesis to my father late B. Brahma Chary, mother B. Sathya laxmi, my brother B. Ravindra Chary, my wife B. Shailaja, and my kids B. Rahul, B. Adharsh for their encouragement and support.

I would also like to dedicate this to my Prof. Kim Sunggak for his constant support for my entire Ph.D study.
Acknowledgements

Firstly and foremost, I would like to express my deepest gratitude to my supervisor, Nanyang Professor Sunggak Kim for his invaluable guidance, motivation and support throughout my research period. His constant patience, feedback, technical and editing skills were essential to complete my thesis. Professor Sunggak Kim availability, encouragement and scientific integrity have been great value to me. He was more of a well-wisher than a supervisor. Certainly, no words could express my gratitude and I will forever be greatful for his guidance.

I would like to use this opportunity to express my sincere thanks to our collaborator Professor Phil Ho Lee and his group members for their continuous support. Many thanks to my labmates Chan Liyan for revising my thesis, Meng Xiangjian, Kelvin Go Kiat and Nicole Loy.

I would like to thank the CBC staff, Eeling, Wenwei, for their assistance with instrument training/usage such as NMR, LC-MS. My sincere thanks to Celine, for her assistance in administrative matters. I would also like to thank Wei ting for assistance conference matters, Ai Hua and teaching staff for IR, UV instrumentation training.

I would also like to extend deepest gratitude to Nanyang Technological University for providing financial support throughout my Ph. D studies and giving opportunity to attend overseas conference.

I would like to special thanks to my M.Sc professor Sarbani Pal and Dr. Manojit Pal for giving me the motivation to do Ph. D studies. It is a great privilege to work with wonderful and kind human beings like Pal sir and Pal madam.
I would like to say special thanks to my friend lecturer Dr. Sreekumar for revising my thesis and for his help. I also thank my friends Krishna Kishore, Kalyan, Srinivas reddy, Magesh, Prasad and senthil.

Finally, my deepest grateful thanks to my wife Mrs. Shailaja, my kids Rahul, Adharsh, sankeerthana, my heartbeat my brother Ravindra Chary, his wife Rekha, my mother Sathya laxmi, and also my sister Bhagya laxmi, brother in-law Nagaraju for their love, support, understanding and encouragement over the past years. Without my family support this thesis would not have possible. Thanks to one and all.

ABSTRACT

Transition metal-catalyzed reactions are one of the most powerful and direct approaches for the synthesis of organic molecules. During the past several decades, new synthetic methodologies come out continuously. The work of the thesis has been directed towards establishing transition metal-catalyzed functionalization of alkynes and arenes. This thesis is divided into two parts.

Part I: Au(I)-catalyzed addition of diphenyl phosphate, Brønsted acids to alkynes and their further applications.

Part II: Pd- and Rh-catalyzed functionalization of arenes using organophosphoryl directing groups

In Part I, we demonstrated Au(I)-catalyzed regio- and stereo-selective addition of diphenyl phosphate to alkynes to furnish kinetically controlled the Markovnikov products and their isomerization to thermodynamically stable enolates. This methodology also extended to other Brønsted acids like carboxylic acids and sulfonic acids.

To extend this approach, application of this methodology on haloalkynes provided Z-halo vinyl phosphates in a regio- and stereo-selective manner, whereas consecutive Pd-catalyzed cross-coupling reaction of Z-halo vinyl phosphates gave stereodefined trisubstituted olefins. In addition, alkynyl hydrogen phosphate in an endo- or exo-dig ring closure provided a variety of cyclic vinyl phosphates under very mild conditions.

In Part II, due to importance of organophosphates in biological and organic chemistry, we aimed to explore C-H activation reactions of arenes using phosphoryl related directing groups. In Chapter V, we developed a novel Pd(II)-catalyzed protocol for C–H arylation at room temperature in which the phosphoramide group was utilized as a directing
group for the first time. Diaryliodonium triflates were used as an aryl source for these reactions.

In Chapter VI, Rh(III)-catalyzed *ortho*-olefination reactions of dialkyl arylphosphonates were studied. In this mild and efficient process, the phosphonic ester was utilized successfully as a new directing group. In addition, mono-selectivity for unsubstituted substrates using a phosphonic diamide directing group was also achieved.

Chapter I. Gold-Catalyzed Nucleophilic Addition to Alkynes

1.1 Introduction

Gold catalyzed organic transformations have emerged as a powerful tool in organic synthesis.¹ Gold is a precious metal for coinage, jewellery and art work used by all the civilizations. It is also used in dental medicine and treatment of arthritis. Recently, gold has been recognized as a soft Lewis acid, which allows activation of soft electrophiles such as the unsaturated system alkynes, alkenes, and allenes, to build carbon–carbon and carbon–heteroatom bonds under mild conditions. The recent enormous interest on gold catalysis has been reflected in excellent reviews and publications in the literature over the past two decades. During the past ten years, several research groups have developed gold-catalyzed homogeneous catalytic reactions. Gold exhibits +0, +1 and +3 oxidation states in organic solvents. In the absence of stabilizing ligands, gold(I) spontaneously disproportionates to gold(III) and gold(0) in aqueous solution. Gold catalysts are simple, operationally safe and exhibits high tolerance to oxygen in contrast to other metals. The apparent redox stability of gold(I) species allows new modes of reactivity. Gold is naturally abundant and the cost is also comparable to the palladium, platinum and rhodium, which are used in industrial applications.

In 1973, a milestone work reported by G. C. Bond involved silica or alumina supported gold catalyzed hydrogenation.² In 1986, Ito–Hayashi reported a gold catalyzed asymmetric aldol reaction for the first time.³ Subsequently, Utimoto⁴ and Teles⁵ initiated an impressive growth of activities on homogeneous gold catalysis. In the field of total synthesis, gold catalysis turned out to be useful for the synthesis of many natural products as the methods have mild reaction conditions and high functional group tolerance. Most of the retrosynthetic disconnections of natural product include the formation of furans,
pyrans, esters, ketones and acetics from alkynes. Figure 1.1 highlights a list of selected natural products involving gold catalysis in the field of total synthesis.

![Figure 1.1 Gold-catalysis involved in the area of total synthesis](image)

**1.2 Importance and Properties of Gold**

**1.2.1 Characteristics of Gold**

Gold represented as Au derived from Aurum (Latin name) and the atomic number 79. The electronic configuration of gold is Xe 4f^14 5d^10 6s^1. According to orbital diagram, the bond between metal and π ligands depends on four components, in which two of them are important in bond energy. The in-plane π orbital make σ symmetric L → M donation and π-symmetric M → L back donation. As per high level computational method the parent Au^+ acetylene and Au^+ ethylene accounted about 65% σ interaction and 27% π interaction. It was established that the back bonding observed was of higher percentage. In gold carbonyls, the back donation was found negligible by characterizing spectroscopic method as the (υ_c-o) frequency was observed greater than that of free CO. These observations clearly demonstrate high reactivity of gold towards π ligands.
Alkynophilicity dominates over alkenophilicity because alkynes have lower LUMO than alkenes. Alkenes are more electrophilic and less nucleophilic than alkynes.

1.2.2 Relativistic Effect

Alkynophilicity of gold can be explained by strong relativistic effects. For heavy metals, relativistic effects are crucial to understand the electronic structure. Heavy transition metals have highly positive nucleus where by the electrons is liable to have heavier consequences contraction of orbitals closer to nucleus. Strong Lewis acidity of gold is due to the relativistic contraction of s and p orbitals towards nucleus and the expansion of the 5d and f orbital is due to the shielding effect of contracted core. All these will lead to the decrease of bond length and lower the nucleophilicity (lower affinity for oxidative addition). The LUMO of the s orbital is the first acceptor to receive electron density from the HOMO π system causing an increase in the π acidity. The electronegativity of gold is higher in 11th group elements (copper 1.9, Ag 1.9, Au 2.4) and is comparable to iodine (2.2).

1.2.3 Pull-Push Reactivity

Gold catalyzed acetylenic Schmidt reaction is the best example to explain the pull-push reactivity of gold. Gold is considered to be a π acid which depletes electron density. Gold can also back-donate electron density in which creates both nucleophilic and electrophilic character on vicinyl carbon of an alkyne. Azide 1 will undergo 5-endo-dig cyclization followed by back donation of electron density from gold. This leads to the liberation of nitrogen and gold carbene 1b which is then stabilized by 1,2-alkyl shift. Finally, protodemetallation of gold and aromatization give the heterocycle 2 (Scheme 1.1).
1.2.4 Gold Catalysis (between 1970-2000)

Gold catalyzed organic transformations are atom economic. It usually has mild reaction conditions, different reaction scope and high tolerance to functional groups. In 1976, pioneering work from Thomas et al. reported the first gold catalyzed addition of aqueous methanol to alkynes. When the alkyne is treated with aqueous methanol in the presence of a catalytic amount of tetrachloroauric acid, the corresponding ketone was obtained as a major product together with methyl vinyl ether and vinyl chloride as the minor products (≤ 5%) (Scheme 1.2).\(^9\)

\textbf{Scheme 1.3} Gold-catalyzed nucleophilic hydroamination to alkynes
In 1987, Utimoto et al. demonstrated intramolecular hydroamination of alkynes in the presence of 5 mol% Na(AuCl)₄ catalyst to give cyclic imine via enamine intermediate.⁴a

In 1986, Ito-Hayashi reported the gold catalyzed aldol reaction for the first time. Treatment of an aldehyde with methyl isocyanoacetate in the presence of generated bis(cyclohexylisocyanide)gold(I)tetrafluoroborate insitu catalyst afford the product (3 : 4 ratio 89:11) in 95% yield at room temperature in dichloromethane.³

Scheme 1.4 Gold(I)-catalyzed asymmetric aldol reaction of alkynes

In 1998, Teles first introduced the new class of air and water sensitive cationic gold(I) complexes for the addition of alcohol to alkynes. They used methyl(triphenylphosphane)gold(I) as a gold source and methanesulfonic acid as cocatalyst which gave addition products. These gold(I) catalysts are water and air sensitive and the reactions can be performed under neat condition.⁵a,b

Scheme 1.5 Gold(I)-catalyzed addition of alcohol to alkynes
In 2000, Hashmi demonstrated gold-catalyzed synthesis of phenol from furanyl alkyne derivatives. \(^{10a,b}\)

![Scheme 1.6 Gold-catalyzed synthesis of phenol](image)

1.3 Gold-Catalyzed Nucleophilic Additions

Transition metal mediated nucleophilic addition onto the alkyne is atom economic, thus fulfilling the requirement of green chemistry. Gold(I) and gold(III) are highly efficient Lewis acids to catalyze nucleophilic addition reactions onto alkynes. Au(I) and Au(III) homogeneous catalysis has emerged as an efficient tool to activate triple bonds for the addition of various nucleophiles. The most generally and extensively used chemical transformation of carbon-carbon multiple bonds is the addition of E-Nu (E= H, BR\(_2\), Si, Sn, and the Nu = halogen, CN, CHO, OH, CO, COOR, NR\(_2\), etc.) across the multiple bond. Alkynes are frequently used as reactive partners in gold catalysis. In addition to its ability to activate alkynes and related substrates, the catalysis of nucleophilic addition by gold complexes for the formation of carbon–carbon and carbon–heteroatom bonds has been one of the most investigated reactions in organometallic catalysis.
The general mechanism for nucleophilic addition involves the coordination of gold catalyst with alkyne to form an Au-π-alkyne complex. The nucleophilic attack on triple bond \textit{anti} to the gold which then forms a vinyl gold complex. Finally, protodemetallation of gold will give the nucleophilic addition product (Scheme 1.7).

In this chapter, we mainly focused on gold-catalyzed nucleophilic additions associated with alkynes as substrates. Nucleophile can be hetero atom which consists of nitrogen and oxygen. My research focused on \textit{O}-nucleophilic addition and its corresponding transformation.
1.3.1 Gold Catalyzed Addition of N-Nucleophiles

Gold catalyzed N-nucleophile addition on C-C multiple bonds is an efficient method to prepare nitrogen-containing compounds. Nitrogen heterocycles are important structural units in many drugs and materials. After the finding of gold catalyzed intramolecular hydroamination by Utimoto in 2003, the first intermolecular hydroamination was reported by Tanaka and his coworkers. They reported addition of aromatic amines to alkynes under solvent free conditions using methyl triphenylphosphine gold(I) and H₃PW₁₂O₄₀ (phosphotungstic acid) as a acidic promoter, which affords ketimines in good yields (Scheme 1.8).

**Scheme 1.8** Gold(I)-catalyzed intermolecular hydroamination of alkynes

To prepare N-Heterocycles, Li and coworkers reported double hydroamination of o-alkynylaniline with terminal alkynes using 5 mol % of AuCl₃ and 5 mol % AgOTf (Scheme 1.9). The corresponding N-Vinylindoles were obtained up to 17-88% yields. Mechanistic studies revealed that it follow through an intermediate before of C-N bond formation.

**Scheme 1.9** Gold(I)-catalyzed double hydroamination of o-alkynylaniline
1.3.2 Gold-Catalyzed Addition of O-Nucleophiles

Gold-catalyzed addition of O-nucleophiles to non-activated C-C triple bond is considered an attractive method to prepare functionalized ketones, ethers, acetics, lactums, vinyl esters and mainly O-heterocycles. Hydration of alkynes leads to ketones is a useful transformation in organic synthesis. Previously, hydration of alkynes known with mercury salts requires harsh acidic conditions.\textsuperscript{13} Utimoto then developed a method where by treatment of an alkyne with 2 mol\% sodium tetrachloroaurate in methanolic water which affords the corresponding ketones in excellent yield (Scheme 1.10).

\begin{center}
\textbf{Scheme 1.10} Gold(I)-catalyzed hydration and MeOH addition to alkynes
\end{center}

Later Hayashi and Tanaka hypothesized high turnover frequency in hydration of alkynes using PPh\textsubscript{3}AuMe and AgSbF\textsubscript{6} as a cocatalyst in the presence of acidic promoter.\textsuperscript{14} Higher catalyst loading and the requirement of concentrated solution of strong acids are required to achieve higher yields are the major drawbacks of this reaction. Recently Nolan reported improved hydration of alkynes using gold carbene as catalyst under acid free conditions.\textsuperscript{15}

Gold-catalyzed preparation of oxygen-containing heterocycles can be achieved using alkynes as substrates. Furan and dihydrofuran derivatives are synthetically valuable in pharmaceuticals and the key subunit in many natural products.
Chapter 1

Scheme 1.11 Various approaches towards synthesis of furan derivatives under gold conditions

Many groups have thus reported gold catalyzed synthesis of furan derivatives. Furan moiety can be constructed by intramolecular attack of alcohol on to alkynes or allenes. The alcohol can be present in the starting material 7, 8 or formed \textit{insitu} from epoxides 3, 4, 5, carbonyls 6, 7 or acetates 6 (Scheme 1.11).

Scheme 1.12 Aldehyde involved gold(I)-catalyzed cyclization

Belot reported Au(I)-catalyzed tandem acetalization and subsequent cyclization of 3-nitro-2-alkynyl aldehyde The reaction can also proceed in the absence of the Brønsted acid (Scheme 1.12).
In 2000, Hashmi reported cycloisomerization of 9 using gold(III) catalyst under ambient condition in acetonitrile. Encouraged from this work, Liu reported in 2005, the gold catalyzed synthesis of substituted dihydrofurans 10 and furans 11 using common intermediate (Z) enynols 9. Gold(I) and gold(III) gave comparable yields and the cyclization proceeded in a 5-exo-dig fashion with high regioselectivity (Scheme 1.13).\(^{18}\)

\[
\text{Scheme 1.13 Gold-catalyzed stereo selective cyclization and cycloisomerization}
\]

Acetals are used as protecting groups in organic synthesis. The conventionally preparation involves the addition of alcohol to aldehyde or ketone under acidic conditions. The removal of water is necessary to obtain acetals in good yields. A variety of acetals including spiroketals, monocyclic, and bicyclic ketals are obtained via gold catalysis under mild conditions. Gold catalyzed synthesis of strained bicyclic ketals 13 was reported by Michelet and Genêt whereby two intramolecular hydroxyl groups 12 were utilized as nucleophiles for double cycloisomerization in methanol.\(^{19}\)

\[
\text{Scheme 1.14 Gold-catalyzed cycloisomerisation of homopropargylic diols}
\]

After this, Krause claimed that gold catalyst is able to mediate cycloisomerization–hydroalkoxylation. Mechanistic studies provide evidence that tetrahydrofuranyl ether is
obtained with 10 mol % Brønsted acid.\textsuperscript{20} At about the same time, Barluenga also reported similar type of cycloisomerization.\textsuperscript{21}

Recently, Sheppard described the formation of boron enolate from gold catalysis under mild conditions. Enolates are carbanionic sources for C-C bond forming reactions.\textsuperscript{22} The corresponding \(O\)-alkynyl boronic acid \(14\) underwent cyclization in \textit{6-endo dig} mode to give boron enolate \(14a\) using 1 mol % \(\text{PPh}_3\text{AuNTf}_2\) in dichloromethane. Further trapping of the boron enolate with various aldehydes affords aldol product \(15\) in excellent yields.

Instead of boron, silicon was also utilized in the similar gold catalytic system.\textsuperscript{23}

\begin{center}
\textbf{Scheme 1.15} Gold-catalyzed enolate formation / aldol reaction
\end{center}

Another classical gold mediated reaction is the rearrangement of esters group.\textsuperscript{24} Classically 1,2- or 1,3- migrations observed with propargylic esters. Furthermore, rearrangement extended not only to esters but also observed with phosphates and halogen.\textsuperscript{25}

\begin{center}
\textbf{Scheme 1.16} Migration of an ester under gold conditions
\end{center}
Despite the lower nucleophilicity of carboxylic acids, acids can also be added to alkynes. It was reported that intermolecular version of gold(I)-catalyzed addition of carboxylic acid to terminal alkynes afford lactones.\textsuperscript{26} In 2006, J. P. Genet and V. Michelet reported gold(I)-catalyzed intramolecular cyclization of acetylenic acid at room temperature leading to $\gamma$-lactones (Scheme 1.17).\textsuperscript{26a} Furthermore, the reusable gold deposited on zeolite is used efficiently for this transformation.\textsuperscript{27}

Scheme 1.17 Gold(I)-catalyzed cycloisomerization of alkynes

Fürstner reported seven membered lactones by using enynyl esters through gold cycloisomerization process.\textsuperscript{28} Inspired from the above works, intermolecular addition of acid to alkynes generate vinyl esters has been extensively studied with several transition metals other than gold. High reactivity, alkynophilicity and chemo-selective nature of gold would give a variety of the modifications to alkynes under gold catalysis.
Proposed work

The work of this thesis is directed towards the gold catalyzed nucleophilic additions on to alkynes. Addition of nucleophiles to alkynes is perfectly atom economic, mild and fulfils the requirement of green chemistry. However, the nucleophilic additions are known to suffer from regio- and stereo selectivity issues. Enol phosphates and enol esters are versatile building blocks for many organic transformations in organic synthesis. Therefore, the most straight forward technique to prepare enol phosphates and enol esters involves metal catalyzed addition of acid to alkynes. In the literature, we found that an enol phosphate was used as coupling partner in cross coupling reactions.

The aim of this project is to develop stereo- and regio-selective addition of diphenyl phosphate to alkynes using gold catalyst. We envisioned that upon addition of diphenyl phosphate to alkynes will provide the corresponding enol phosphates. However, there is a possible competition between kinetic and thermodynamic isomers. The selective preparation of kinetically controlled Markovnikov addition product and thermodynamical stable enolates will be one of the subjects we plan. Furthermore, this methodology will be extended to investigate other Brønsted acids resembling carboxylic acids. The behavior of sulfonic acids will be investigated in the area of stereo and regio- selectivity of addition reactions.

Extension of this approach will be expanded to intermolecular addition of diphenyl phosphate to haloalkynes. Although halides are used as a cross coupling partner, vinyl phosphates also proved as a electrophiles in cross coupling reactions. We will explore palladium-mediated cross coupling reactions of the addition products derived from alkynes and halo alkynes. Furthermore, cyclic vinyl phosphates formed from intramolecular cyclization of alkynyl hydrogen phosphate are also interesting intermediates for further functionalization.
Scheme 1.18 Gold(I)-catalyzed functionalization of alkynes and halo alkynes
Chapter II. Gold(I)-Catalyzed Hydrophosphoryloxylation of Alkynes

2.1 Introduction

Enol phosphates are synthetically versatile intermediates due to the importance in various organic transformations. Enol phosphates are stable, readily accessible, and used as versatile electrophiles. Synthesis of enol phosphates is simple and involves quenching of lithium enolates with the corresponding phosphorochloridates. Enol phosphates are used as cross coupling partners in many cross coupling reactions like Suzuki, Heck, Kumada and Stille reaction. However, the selectivity is the main drawback of this transformation. It is difficult to get the selectivity (kinetic and thermodynamic) of the formed products. Even under equilibrium conditions for unsymmetrical ketones, thermodynamic enol phosphates predominate but cannot get exclusively.

In 1998, Tanaka demonstrated ruthenium-catalyzed addition of diphenylphosphinic acid to terminal alkynes for the first time. As far as we know, it was the only report described the metal catalyzed preparation of enol phosphosphinates. The Markovnikov addition products were achieved with high regioselectivity using 2.5 mol % of Ru(CO)$_{12}$ in toluene at 140 °C for 5 h. These reactions required harsh conditions to obtain the desired products. Moreover, it was noteworthy that the reaction was unsuccessful with the addition of diphenyl phosphate to alkynes.

\[ R \equiv H \rightarrow \begin{array}{c} \text{Ph} \end{array} \text{POH} \xrightarrow{2.5 \text{ mol} \% \text{ Ru(CO)}_{12}} \begin{array}{c} \text{Ph} \end{array} \text{POH} \]

\[ R = \text{alkyl, aryl} \]

**Scheme 2.1** Ruthenium mediated Phosphinic acid addition to alkynes

Due to the wide variety of applications of enol phosphates in organic synthesis, there is a need to develop a new efficient metal catalytic system for the regioselective synthesis of...
enol phosphates. The high alkynophilic character of gold drove us to study the regioselective preparation of enol phosphates using gold as a catalytic system.

### 2.2 Intermolecular Addition of Diphenyl Phosphate to Alkynes

#### 2.2.1 Results and Discussion

To examine the feasibility of hydrophosphoryloxylation, 1-octyne (16a) was used as a model substrate. The reaction did not occur with gold(III) catalysts and when gold(I) catalyst was used alone (Table 2.1, entries 1, 2). Non-coordinating counter ions like Ag salts were added to determine whether it would generate active cationic Au catalyst. Interestingly, when the reaction was carried out using 5 mol % PPh₃AuCl and 5 mol % AgPF₆, the kinetically controlled Markovnikov addition product 17a was obtained in 88% yield in 9 h at room temperature (Table 2.1, entry 7). AgBF₄ is less effective and afforded the corresponding addition product in 72% yield (Table 2.1, entry 6). Combination of

gold(I) with AgSbF$_6$ and AgNTf$_2$ was ineffective as well (Table 2.1, entry 5, 8). The reaction did not work in presence of protic acids like TfOH (Table 2.1, entry 9). The reaction did not proceed in solvents like dichloromethane, acetonitrile, nitromethane and ethanol. Toluene was found to be the solvent of choice for the reaction.

**Table 2.3 Preparation of Kinetic Enol Phosphates$^a$**

This catalytic system was also successful for the addition of diphenyl phosphinic acid to alkynes to obtain the corresponding vinyl phosphinates 17g and 17h in 90% and 70%
yield respectively (Table 2.3). Hydrophosphoryloxylation of phenyl acetylene did not proceed at room temperature and required heating at 60 °C for 12 h (Table 2.3). Addition of diphenyl phosphate to activated alkynes such as ethyl propionate and phenyl propionate took place via trans addition in a stereo- and regioselective manner to afford enol phosphates 17c and 17e with 84% and 78%, respectively (Table 2.3). After successive addition of diphenyl phosphate to terminal alkynes, we tried to add diphenyl phosphate to symmetrical alkynes. Symmetrical alkynes are less reactive than terminal alkynes thus needing to reflux to 110 °C in toluene for 15 h to obtain addition product 17f in 72% yield (Table 2.3).

2.2.2 Addition of Diphenyl Phosphate to Haloalkynes

We next studied the addition of diphenyl phosphate to haloalkynes. Since the regio- and stereo-selective hydrophosphoryloxylation would provide alkenyl halophosphates, this approach would provide an easy access to stereodefined trisubstituted alkenes via sequential transition metal catalyzed cross coupling reactions.

Scheme 2.2 Gold-catalyzed regio- and stereoselective synthesis of alkenyl halophosphate

Haloalkyne 18 was prepared by the treatment of terminal alkyne with N-iodosuccinimide or N-bromosuccinimide in the presence of a catalytic quantity of silver nitrate in acetone at room temperature for 3 h. The initial experiment was carried out with diphenyl phosphate and 1-iodooctyne in the presence of 5 mol % PPh₃AuCl and 5 mol % AgPF₆ in toluene at room temperature for 6 h. Reaction proceeds cleanly, yielding 80% of product.
The same experiment was then repeated with the replacement of AgPF$_6$ with AgOTf and it was found to proceed smoothly at room temperature in 4 h to yield 19a at 90% yield (Scheme 2.3). The geometry of the product formed was determined by NOESY analysis which clearly showed that the product was (Z)-alkenyl iodophosphate. There is a correlation between alkyl group and hydrogen. The hydrophosphoryloxylation of iodoctyne was regio- and stereo-selective and afforded a single product.

2.1 Figure NOE correlation of alkenyliodophosphate

When hydrophosphoryloxylation of several iodo-and bromoalkynes was carried out under the same conditions, the corresponding (Z)-alkenyl halophosphates were isolated in high yields. The addition of diphenyl phosphate to 1-bromodecyne and 1-iodohexyne gave the corresponding (Z)-alkenyl halophosphates 19c and 19b in 82% and 88% yield (Scheme 2.3) Stereoselective preparation of (Z)-alkenyl halophosphates.
2.3). The reaction equally worked well with aliphatic haloalkynes as well as aromatic haloalkynes.

Hydrophosphoryloxylation of iodophenylacetylene and phenethylidooacetylene also gave alkenyl iodophosphate \( \text{19d} \) and \( \text{19f} \) in 80% and 76% yield (Scheme 2.3). The electron-withdrawing groups did not influence the addition, giving the (Z)-alkenyl halophosphate \( \text{19g} \) and \( \text{19h} \) in 85% and 72%, respectively (Scheme 2.3). The regioselectivity was controlled by the electron-withdrawing effect of the iodo group rather than the resonance effect, although the regioselectivity is normally governed by the resonance effect. In addition, the stereoselectivity is attributed to the trans-addition of nucleophiles to vinyl gold complex (Scheme 2.4).\(^{36}\)

Scheme 2.4 Plausible mechanism for addition of diphenylphosphate to haloalkynes

2.2.3 Stereoselective Synthesis of Trisubstituted Alkenes

The synthesis of stereodefined trisubstituted alkenes is very important in organic synthesis. The skeleton of the trisubstituted alkene is seen in many biologically active compounds and many ingenious approaches have been reported.\(^{37}\) Among various approaches, one of the most attractive approaches is to utilize the transition metal-mediated cross-coupling reactions of stereodefined alkenyl derivatives and depends very much on the regio- and stereospecific synthesis of alkenyl derivatives from alkynes.\(^{38}\)
In 1988, H. C. Brown reported highly regio- and stereoselective synthesis of trisubstituted alkenes using boration of alkynyl halide followed by treatment of alkyl lithium or Grignard reagents. Following this seminal work, Negishi utilized alkenyl boranes prepared from the bromoboration of alkyne followed by tandem Pd-catalyzed cross coupling reactions to achieve (Z)-trisubstituted alkenes.

Scheme 2.5 Previous approaches towards synthesis of trisubstituted alkenes

Recently, Huanfeng reported trisubstituted alkenes via iodination of alkynyl halides using potassium iodide as iodine source. The above reports inspired us to prepare stereo- and regio-selective trisubstituted alkenes from alkenyl iodophosphate which prepared from gold(I)-catalyzed addition of diphenyl phosphate to haloalkynes.

To develop a stereoselective synthesis of trisubstituted alkenes using alkenyl halophosphates, first we focused on the Sonogashira coupling reaction using alkenyl iodophosphate 19a. Among several palladium catalysts screened for this reaction, Pd(PPh₃)₄ was the best catalyst for the Sonogashira reaction. The best result was obtained
by treatment of 19a with phenylacetylene in the presence of 2 mol % of Pd(PPh₃)₄, 10 mol % of CuI and 3 equiv of triethylamine in 1,4-dioxane (Table 2.4, entry 5). The reaction proceeded at room temperature for 2 h and the iodo group underwent the preferential and clean coupling reaction in the presence of a phosphate group.

ᵇ 2 mol % Pd(PPh₃)₄, 10 mol % CuI and 3 equiv of Et₃N were used.
ᶜ 4 mol % Pd(PPh₃)₄ was used.

Use of other solvents like THF, toluene, DCE, and DMF afforded the corresponding Sonogashira coupled product 20a in moderate yield (Table 2.4, entry 7–9). In contrast, 1,4-dioxane is the solvent choice of this reaction. Increment of the catalyst loading to 4 mol % of Pd(PPh₃)₄, slightly increased the yield of the product to 84% (Table 2.4, entry
6). The addition of Na₂CO₃ and K₂CO₃ did not improve the yield (Table 2.4, entry 11, 12) and triethylamine was the most effective among the bases used.

Having the optimum condition in hand, we investigated the scope of the Sonogashira coupling of alkenyl iodo phosphates with other alkynes. Several alkenyl iodophosphates worked well with phenyl acetylene using the standard condition to obtain the corresponding Sonogashira products 20b and 20e in good yields (Table 2.5). Different nucleophiles like bromo phenylacetylene and 4-methoxy phenylacetylene underwent the Sonogashira reaction to give the corresponding coupled products 20c and 20d in 80% and 88% yield (Table 2.5). But alkyl substituted alkynes gave product 20f and 20g in lower yields (Table 2.5).

*aReaction was carried out using 4 mol % Pd(PPh₃)₄, 3 equiv of Et₃N, and 10 mol % CuI in dioxane at room temperature for 2-3 h.*

The success of the Sonogashira reaction by using the alkenyl iodophosphate prompted us to extend the functional modification through other cross coupling reactions like the Suzuki, Stille reactions etc. When 19a was treated with phenylboronic acid in the presence of 5 mol% Pd(PPh₃)₄, 2 equiv of triethylamine and 3 equiv of K₃PO₄ in THF, the reaction was complete in 16 h, yielding the desired coupling product in 51% yield at 70 °C (Table 2.6, entry 2). The Suzuki coupling in DMF shortened the reaction time to
1.5 h but the yield was reduced to 40% (Table 2.6, entry 1). Similarly, low yields were obtained using toluene and dichloroethane as the solvent (Table 2.6, entry 4, 5). The best solvent for this Suzuki reaction found out to be 1,4-dioxane (Table 2.6, entry 3).

* 50% starting material was recovered.

The Suzuki reaction of 19b furnished the coupled product 21b in 65% yield (Scheme 2.6). Similar results were observed with vinylboronic acid pinacol ester as coupling partner (Scheme 2.7).

Scheme 2.7 Suzuki cross-coupling reaction of (Z)-alkenyl iodophosphate
After the success of the Sonogashira and Suzuki coupling reactions involving alkenyl iodophosphate, we also tried the Stille coupling reaction. When the alkenyl iodophosphate 19 was treated with vinyltributyltin in the presence of 4 mol % of Pd(PPh₃)₄ in 1,4-dioxane at 100 °C for 12 h, the Stille coupled product 22 was isolated in 54% yield. The yield was improved to 61% by performing the reaction in toluene. Alteration of Pd catalyst from Pd(PPh₃)₄ to PdCl₂(PPh₃)₄ gave much better results. The alkenyl iodophosphate 8a was treated with 5 mol % PdCl₂(PPh₃)₄ in DMF with vinyl tributyltin to yield 22a in 93% yield at room temperature.

![Scheme 2.8 Pd-catalyzed Stille reaction of alkenyl iodophosphate](image)

### Scheme 2.8 Pd-catalyzed Stille reaction of alkenyl iodophosphate

#### 2.2.4 Synthesis of Trisubstituted Olefins

To complete the stereoselective synthesis of trisubstituted olefins, we turned our attention to the cross coupling reactions using vinyl phosphates. It was documented that vinyl phosphates were used as electrophiles in many cross coupling reactions. However, we found only few reports using unactivated vinyl phosphates with Grignard reagents. In 2009, Skrydstrup reported ligandless Pd-catalyzed Kumada-Corriu coupling reactions using vinyl phosphate. This attracted us to complete the stereoselective synthesis of trisubstituted olefins.⁵ᵃ Treatment of vinyl phosphate with aryl magnesium halide in the presence of 2 mol % PdCl₂ in THF afforded 1,1-disubstituted alkenes. This reaction is simple, economic and does not require any phosphine ligands.
When Sonogashira coupled products 20 was subjected to the Kumada-Corriu condition with PhMgBr using 5 mol % of PdCl$_2$ in THF, the desired trisubstituted product 25 was obtained in good yields. The reaction was fast and could complete within 10 min at room temperature. The ligandless condition is appropriate to a variety of alkenyl and aryl phosphates which afford the corresponding trisubstituted alkenes 25a-25d in better yields (Scheme 2.10). When we treated Suzuki coupled product 21 with PhMgBr in the presence of 2 mol% PdCl$_2$ as a catalyst in THF, the reaction proceeded at room temperature and afforded 23a and 23b in 72% and 62% yield, respectively (Scheme 2.10). In the case of 23a, a small amount of (E)-isomer was observed. Finally, Stille coupled products 22 equally furnished (Z)-trisubstituted alkenes 24a and 24b in 65%, 70% yield under the similar conditions (Scheme 2.10). We developed a highly efficient method for a stereodefined synthesis of trisubstituted alkenes via hydrophosphoryloxylation of iodo alkynes and subsequent consecutive pd-catalyzed cross coupling reactions.
Scheme 2.10 Preparation of trisubstituted olefins using Kumada-Corriu coupling
2.3 Intramolecular Addition of Diphenyl Phosphate to Alkynes

2.3.1 Introduction

After the successful regioselective addition of diphenyl phosphate to alkynes and haloalkynes, we turned our attention towards intramolecular addition of P-OH bond to alkynes. Intramolecular addition of P-OH to the alkyne leads to a new class of phosphorous containing heterocycles, which is more precious in biologically active natural products as well as synthetic intermediates. Synthesis of these phosphorous heterocycles has not been studied actively in the recent years. In 2003, Ding reported Cu-catalyzed cyclization of o-ethynyl phenylphosphonic acid monoester at 90 °C in DMF. The reaction afforded phosphaisocoumarins in excellent yields (Scheme 2.11). This method was useful for the preparation of variety of 3- and 7- substituted phosphaisocoumarins. The same research group also studied silver-catalyzed cyclization of 27 (Scheme 2.11).

Scheme 2.11 Intramolecular cyclization of alkynyl phosphonic acid monoester

In our studies, we investigated the possibility of using phosphates not only as a tether linker but utilizing the cyclic phosphate for transition metal catalyzed cross coupling reactions.
The ensuing project will enlighten the possibility of cyclization of P-OH groups to alkynes using gold catalysis for the synthesis of new cyclic phosphates.

2.2 Figure New class of cyclic phosphates

2.3.2 Results and Discussion

Alkynyl hydrogen phosphate was used as the starting material for this cyclization. Intramolecular attack phosphoryl P-OH onto gold activated triple bond will afford the cyclized product. The major concern for this cyclization is the regioselectivity. Cyclization can undergo either cyclized 5-exo-dig or 6-exo-dig fashion to give a five-membered cyclic phosphate 30 and/or a six-membered cyclic phosphates 31, respectively (Scheme 2.12).

Scheme 2.12 Possible products from cyclization of alkynyl hydrogen phosphate

The alkynyl hydrogen phosphate can be prepared by treating of an alkynol with phosphorodichloridate using triethylamine in THF. Subsequent hydrolysis of corresponding Chloroalkynyl hydrogen phosphate gave the alkynyl hydrogen phosphate 29 in good yields. Previously, phosphoryl transfer reaction was mainly achieved by using Lewis acids, particularly by TiCl₄.⁴⁵
We tried this reaction in the absence of the Lewis acid. Treatment of propargyl alcohol with 1.2 equiv phosphorodichloridate in the presence of 1.2 equiv of triethylamine followed by the addition of water to afford the desired product 29 in 66% yield with 20% of dialkylated product 32. The yield could be improved to 75% by adding an excess amount of phosphorodichloridate to propargyl alcohol. Triethylamine was added slowly at 0 °C for 30 mins, followed by the addition of excess water at room temperature for 3 h (Table 2.7). Several alkynyl hydrogen phosphates could be prepared under the standard condition.

**Table 2.7** Alkynyl hydrogen phosphates
Secondary alcohols also worked well. However, the method was not useful in preparing tertiary alkynyl hydrogen phosphate.

Initially 29a was used as a model substrate for the cyclization reaction under various conditions. Dichloromethane was chosen as a solvent for this cyclization. This reaction also proceeded in toluene, but needed longer reaction time with comparable yield achieved with dichloromethane. No reaction was observed with silver catalyst alone (Table 2.8, entry 1, 2). Surprisingly, the reaction did not proceed using gold(I) and silver hexafluorophosphatate under the standard condition (Table 2.8, entry 4). Furthermore the combination of triphenylphosphine gold(I) chloride and silver tetrafluoroborate was effective in affording cyclized product 31a in 62% yield (Table 2.8, entry 3). The triphenylphosphine gold(I) chloride and AgOTf catalytic system was most effective and proceeded exclusively by 6-endo dig to give the cyclisation product 31a in 94% yield.

a Yields of isolated product.
indicating that 6-endo-ring closure was favoured over the 5-exo-dig closure (Table 2.8, entry 5).

The reaction did not proceed with protic acids like PTSA and TfOH (Table 2.8, entry 11, 12). Similarly, the cyclization did not proceed with other transition metal catalysts like FeCl₃, PtCl₂, InBr₃, and Sc(OTf)₃ (Table 2.8, entry 6, 8, 9, 10). The active catalyst Fe(OTf)₃ formed with the combination of FeCl₃ and AgOTf, also afforded cyclised product in 63% yield under reflux conditions (Table 2.8, entry 7).

Having the optimum condition in our hand, we investigated the scope and limitation of various alkynyl hydrogen phosphates for gold catalyzed cyclization. This strategy was very useful to synthesize a new class of cyclic phosphates. Propargyl derived alkynyl hydrogen phosphate 29b and 29e undergo 6-endo-dig cyclization to give 6 membered cyclic phosphates 31b and 31c in very good yields. 6-endo-dig is more favourable than 5-exo-dig cyclization. Homopropargyl derived alkynyl hydrogen phosphate 29d (Table 2.7) undergo 6-exo dig cyclisation to obtain 6-membered cyclic phosphate 31d with exomethelene double bond (Table 2.9). This methodology is also useful in preparing 7-membered cyclic phosphates. When 29h (Table 2.7) was subjected for cyclisation, the reaction proceeded smoothly via 7-exo-dig ring closure to afford 31h in 82% yield (Table 2.9).

* diastereomeric ratio

It would be possible to further functionalizing the cyclic phosphate by placing an iodo group at the vinylic position to C-C bond forming reaction. The cyclization of 29g and 29i (Table 2.7) was regio- and stereoselective and afforded the corresponding cyclic phosphates 31f and 31i in 85% and 78% yield, respectively (Table 2.9). For the cyclization of 29f (Table 2.7), two compounds 29e were isolated in 1:1.2 ratio of the E-Z isomers. These structures were confirmed by NOESY NMR analysis.

The cyclization didn’t occur to the secondary alkynyl hydrogen phosphate 29c (Table 2.7), even at reflux in dichloromethane for 12 h. The reason why the cyclization did not proceed is not clear and may be due to the steric hindrance between adjacent CH3 group and gold complex. The bulkiness may have hindered the gold complex from approaching the alkynyl group in a close enough proximity to coordinate to the alkynyl group and to activate it, thus vinyl gold could not be formed.
Figure 2.2 Steric hindrance between gold and CH₃ group

29j (Table 2.6) undergone cyclization reaction, and two isomers of 31j were isolated in 80% total yield (Table 2.9, 1.7:1 diastereomeric ratio).

Mechanism of this cyclisation may involve intramolecular attack of P-OH to the gold activated alkyne to form vinyl gold complex, which would under protodeauration to give the desired cyclic phosphate (Scheme 2.14).

Scheme 2.14 Plausible mechanism for gold-catalyzed 6-endo-dig cyclization

2.3.4 Application of Cyclic Phosphates in Cross-coupling Reactions

We successfully utilized vinyl phosphates as a coupling partners in cross coupling reactions in the initial part of this chapter. We briefly studied the use of this cyclic phosphate for C-C bond formation.
When 31f subjected to Stille coupling condition, the reaction proceeded at room temperature with 5 mol % of Cl₂Pd(PPh₃)₂ in DMF and afforded the Stille coupled product 33 in 84% yield. When the same substrate applied for the Sonogashira condition, gave the coupled product 27 was isolated in 78% yield. Cyclic vinyl phosphates 31d and 31h did not react under the Sonogashira and the Stille reactions conditions (Table 2.9).

When cyclic vinyl phosphates 31d and 31h were treated with PhMgBr and 2 mol % PdCl₂, we were curious whether the cleavage would occur at vinylic C-O or at sp³C-O bond. After reduction with lithium aluminium hydride gave the 36a in 77% yield. Similarly, seven-membered cyclic phosphates also worked well gave the 36b in 85% yield.

**Scheme 2.6** Cross coupling reactions of 31f

**Scheme 2.7** Kumada-Corriu coupling of cyclic vinyl phosphate
2.4 Conclusion

We have developed a gold(I)-catalytic system for inter- and intramolecular addition of phosphoric acid to alkynes and haloalkynes. Intermolecular hydrophosphoryloxylation of alkynes provided the kinetically controlled Markovnikov addition products in excellent yields. Application of this methodology on haloalkynes provided Z-halo vinyl phosphates in a regio- and stereo-selective manner and consecutive Pd-catalyzed cross-coupling reaction of Z-iodo vinyl phosphates gave stereodefined trisubstituted olefins. In addition, cyclization of alkynyl hydrogen phosphate in an endo- or exo-dig ring closure provided a variety of cyclic vinyl phosphates under very mild conditions.
Chapter III. Gold(I)-Catalyzed Addition of Brønsted Acids to Alkynes

3.1 Introduction

Despite the apparent simplicity of addition reactions to alkynes, it is still an important goal to control the regioselectivity of such processes. In chapter II we demonstrated that inter- and intramolecular additions of phosphoric acids to alkynes could be successfully achieved by using gold(I) catalyst. Subsequently, we wanted to expand this strategy to other Brønsted acids like carboxylic acids and sulfonic acids. The resulting enol-esters are valuable intermediates in organic synthesis for carbon-carbon and carbon-heteroatom bond formation. They have been used for the selective generation of enolates\textsuperscript{46}, acylating agents\textsuperscript{47} under mild conditions. They are also suitable substrates for the access to α–haloketones\textsuperscript{48}, and enzyme-catalyzed kinetic resolution of chiral alcohols.\textsuperscript{49} Alkenyl esters have been involved in cyclopropanation,\textsuperscript{50} Diels-Alder reactions,\textsuperscript{51} [2+2] cycloaddition,\textsuperscript{52} and 1,3-dipolar cycloaddition.\textsuperscript{53} Vinyl acetate, acetoxy styrenes, and vinyl haloacetates are important industrial monomers for the preparation of various polymers and copolymers.\textsuperscript{54} We have been interested in finding out if there are similarities in the mode of action as in the addition of diphenyl phosphate to alkynes and to distinguish any differences in the stereo and regioselectivity of the formed products.

Transition metal-catalyzed addition of carboxylic acids to terminal alkynes is an efficient, atom economic method for the synthesis of 1-alkenyl esters. The electrophilic activation of terminal alkynes by suitable metal catalysts with carboxylic acids provide an easy access of three possible 1-alkenyl esters (one Markovnikov-type adduct \textsuperscript{37} and two anti-Markovnikov-type \textit{E} and \textit{Z} adducts \textsuperscript{38} and \textsuperscript{39}). Therefore, it is interesting and crucial to develop catalyst systems that could induce high regioselectivity and stereoselectivity in the addition reactions. Even now in some reactions it is not possible to get the desired regioselectivity at all.
Scheme 3.1 Possible isomers from the metal mediated addition of carboxylic acid to alkynes

Preparation of enol esters can be achieved by quenching the corresponding aldehyde or ketone with a suitable acid anhydride or acid chloride. The drawback of this method is poor selectivity. Another straightforward method involves the addition of acids to alkynes. Initially, the addition of carboxylic acid to alkynes was carried out with mercury salts. However, the method is not viable due to the toxicity of mercury. Henceforth, several groups extensively studied the addition of carboxylic acids to alkyne with ruthenium as the catalyst.

Scheme 3.2 Ru-catalyzed addition of acid to alkynes

In 1983, Shvo and his co-workers reported Ru$_3$(CO)$_{12}$ catalyzed addition of acetic acid to symmetrical alkynes to afford vinyl esters 40 as a major product along with some rearranged product 41. Following this work, Mitsudo-Watanabe described the selective addition of carboxylic acid in the presence of ruthenium complex, triphenyl phosphine and maleic anhydride to give the Markovnikov addition product as the major.
Later Dixineuf further developed an active catalyst for the regio- and stereo-selective anti-Markovnikov addition of carboxylic acids to terminal alkynes. It was clearly demonstrated that nature of the chelating phosphine ligand on the ruthenium centre control the regio-selectivity of the addition reaction. Afterwards, Gossen developed efficient catalytic systems for the both Markovnikov and anti-Markovnikov addition of carboxylic acids to alkynes with readily available ruthenium complexes.

Addition of carboxylic acids to the terminal alkynes giving enolesters is extensively studied by Ru complexes while is also explored with rhenium, iridium and rhodium complexes. We wanted to study hydroacyloxylation in the presence of gold(I)-catalysts in line with our recent interest in the functionalization of alkynes. The aim of our study is to develop a simple, efficient way to catalyze the addition of carboxylic acids to alkynes with high selectivity. Hubert reported intermolecular addition of acetic acid to 3-hexyne in THF at 60 °C using (triphenylphosphine)gold(I) pentafluoropropionate and boron trifluoride etherate as a cocatalyst which afforded 3-hexene-3-acetate in a very low yield of 6.2% along with 3-hexanone in 12.3% yield. We sought to improve this
unsatisfactory result and to determine the scope and limitation of hydroacyloxylation, by investigating the addition of carboxylic acids to alkynes using gold(I) complexes.

**Scheme 3.4** First report used gold(I) for the addition of AcOH to 1-hexyne

### 3.2 Gold Catalyzed Addition of Carboxylic Acids to Alkynes

#### 3.2.1 Results and Discussion

We initially applied the standard catalyst PPh₃AuCl system using 1-hexyne and benzoic acid in toluene as the solvent. The addition of the acid to alkyne did not proceed with gold alone. However, reaction proceeded after the addition of a silver cocatalyst. The same was true for silver metal catalyst where the reaction did not proceed in the absence of a gold catalyst.

With the standard condition using 5 mol % PPh₃AuCl and 5 mol % AgPF₆ the reaction did not proceed at room temperature. Heating up to 60 °C afforded the kinetically controlled Markovnikov addition product 44 in excellent yields without any isomerisation of the double bond.

² reaction was carried out in to for 15 h using 5 mol % catalyst. ᵃ in the presence of 10 mol % of allyltrimethylsilane.

The spectral data of vinyl benzoate 44a clearly shows the exo-methene at δ 4.83 (s, 1H) and 4.82 ppm (s, 1H).

The efficiency of the coordinating anion AgPF₆ was studied with several cocatalysts such as AgOTf, AgBF₄, AgSbF₆ and AgNO₃ under the same conditions. While changing AgPF₆ to AgOTf, surprisingly instead of the Markovnikoc addition product, thermodynamically more stable enolester was observed in good yields (Table 3.1, entry 1, diastereomeric ratio 1:3.1). The spectral data clearly shows that alkenyl protons of more stable isomerised product 45a appears at 5.23 ppm (t, J = 7.8 Hz, 1H) and 5.09 ppm (t, J = 7.3 Hz, 1H). But 5 mol % PPh₃PAuCl/AgBF₄ catalytic system was less reactive.
compared to 5 mol % PPh₃AuCl/AgPF₆ system and took 80 °C for 8 h resulting in 2:1 mixture of kinetically controlled Markovnikov product and thermodynamically stable isomerised product was observed in good yields (Table 3.1, entry 2). However, the reaction did not occur in the case of AgSbF₆ and AgNO₃ under reflux conditions (Table 3.1, entry 5, 6). The reaction was also carried out in the presence of protic acids like triflic acid and benzenesulfonic acid at 60 °C for 15 h but the formation of the desired product was not observed (Table 3.1, entry 9, 10).

Scheme 3.6 Gold(I) mediated isomerisation

The complete inverse of regioselectivity observed with the AgOTf cocatalyst may be attributed to the isomerisation of the initially formed Markovnikov addition product 44 to the more stable enol benzoate 45. To check whether protic acid participates in the isomerization, the Markovnikov addition product 44a subjected to the standard condition in the presence of 10 mol % of allyltrimethylsilane. Enol benzoate 45a was afforded in 3 h, indicative of the sole participation of PPh₃AuOTf.

Scheme 3.1 Proposed mechanism for gold(I)-catalyzed isomerization
The effect of solvent was briefly studied using Ph₃PAuCl/AgPF₆ catalyst. The examination of solvent effects revealed that toluene is the solvent choice in this reaction. When the reaction was carried out with dichloromethane, acetonitrile, ethanol, and trifluoroethanol using Ph₃PAuCl/AgPF₆ catalyst at 60 °C for 15 h, the reaction did not proceed even at reflux to give any desired products. Traces of the product were observed, when 1, 2-dichloroethane was used as a solvent (Table 3.2, entry 2). The effectiveness of toluene could be due to stabilization of the cationic complex by the formation of arene-gold complex.⁶⁵

*reaction was carried out with 1 equiv of alkyne, 1.2 equiv of acid and 1 ml solvent.

In order to determine the scope and limitations of the method, structurally different alkynes and carboxylic acids using a standard condition of 5 mol% Ph₃PAuCl/AgPF₆ catalyst at 60°C was employed and the experimental results are summarised in table 3.3.

Both aliphatic and aromatic alkynes were used as substrates to be reacted with the different kinds of aromatic and aliphatic acids. Various vinyl carboxylates were obtained in good to excellent yields. It was observed that the addition of acid to phenylacetylene led to a significant amount of *anti*-Markovnikov product 44m and 44n (Table 3.3).

* reaction carried out with 1.2 equiv alkyne, 1 equiv of carboxylic acid.  
  b reaction proceed at room temperature.  
  c ratio of Markovnikov and anti-Markovnikov products.  
  d need 110 °C and 20% starting material was recovered.

It was observed that the acidity had a pronounced effect on the reactivity of the acids. Acids with lower pKₐ reacted at lower temperature. When trifluoroacetic acid was treated with terminal alkyne, the reaction proceeded at room temperature (Table 3.3 entry 44h) in 6 h. Even under strongly acidic conditions, vinyl trifluoroacetates did not undergo further rearrangement to stable isomers. In the case of 44d, the reaction was complete within 3 h. Furthermore, when benzoic acid is replaced with 4-methoxybenzoic acid (Table 3.3, entry 44g), the reaction was incomplete after 24 h. It clearly shows that the reaction rate would depend very much on the acidity of carboxylic acids. Addition of α,β-unsaturated carboxylic acids to alkyne affords the Markonikov addition product 44k, 44l in good yields (Table 3.3). As shown in the table, acrylic acid and trans-cinnamic acid underwent
the Markovnikov addition products 44k and 44l in high yields of 78% and 88% respectively (Table 3.3).

Besides terminal alkynes, internal alkynes were also included in this experimental study. Internal alkynes such as phenyl ethyl propiolate, symmetrical diphenylacetylene were also reacted successfully with acetic acid yielding products 44p, 44q in reasonably good yields (Table 3.3). Addition of acetic acid to diphenylacetylene required higher temperature of 110 °C and longer reaction time to yield the product in 62% yield together with recovery of the starting material (20%). This is due to the steric hindrance of symmetrical alkyne which makes nucleophilic addition harder. Hydroacyloxylation occurred regioselectively

Table 3.4 Gold(I)-catalyzed isomerisation of alkynes

and stereoselectively via conjugative trans-addition in case of conjugated alkyne esters 44o and 44p (Table 3.3). As for AgOTf as the cocatalyst instead of AgPF6 with gold(1) catalyst, 1-hexyne was reacted with benzoic acid and phenylacetic acid at room temperature for 15 h to give the rearranged thermodynamically stable enol benzoate product 45a, 45c in 87% and 86%, respectively. 4-Phenyl 1-butyne was reacted with acetic acid at room temperature for 15 h to give 45d in 82% yield. Treatment with acrylic acid at room temperature for 15 h produced the corresponding product 45b in 68% yield.

46
When AgOTf is used as the cocatalyst, for all the above reactions, the kinetically favoured Markonikov product was first formed and then it isomerized to give final thermodynamically stable rearranged enol benzoate.

We briefly investigated the reaction by using NMR studies. 1-Hexyne was treated with benzoic acid in the presence of 5 mol% PPh₃AuCl and 5 mol % of AgOTf catalytic system in deuterated toluene. Although the reaction was incomplete after 2 h, the Markovnikov addition product was not observed. No reaction was occurred even in 6 h when we used deuterochloroform as the solvent. When the reaction was carried out by using Markovnikov addition product, the isomerisation proceeded very rapidly at ambient temperature. The Markovnikov product (<10%) was observed after 3 h, this clearly shows that isomerization occurs very rapidly.

Interestingly when acetic acid was added to propargyl benzoate under the similar conditions, a mixture of two products was obtained in equal ratio (1:1). During the reaction, the allene benzoate was observed by NMR but the propargyl benzoate was not completely converted to allene benzoate. Spectral data clearly shows that one is the Markonikov addition product 46 and another one is cis-isomer of coupled product 47 (structure was determined by NOESY NMR analysis).

Scheme 3.7 Addition of AcOH to propargyl benzoate
We also studied the addition of carboxylic acids to electron rich substrates like alkynyl sulfides. Previously Braga reported the regioselective addition of TsOH and TFA to alkynyl sulphide to obtain (Z) vinyl tosylates or (Z) vinyl trifluoroacetates in good yields.\(^66\)

\end{align*}
\]

Treatment of phenyl thioalkyne with carboxylic acids in the presence of 5 mol\% \(\text{Ph}_3\text{PAuCl}/\text{AgPF}_6\) in toluene at 60 °C for 15 h afforded ketene thioacetal 48 in moderate yields. Addition of carboxylic acid to phenylthioalkynes 17 was also regio- and stereo-selective but it occurred via syn addition. It is assumed that the reaction propagates through the formation of the allene intermediate 50 before the nucleophilic carboxylate attack from the less hindered side ensue the product (Z) thiovinyl acetate 48b.

**Scheme 3.8** Plausible mechanism of addition acetic acid to alkynylsulfide
The addition of benzoic acid and acetic acid to the alkynyl sulphides in presence of gold catalyst yields single products $48a$, $48b$ in reasonable yields. The addition of formic acid on the other hand, did not give any desired addition product but produced thioester $49$ as a result of the hydrolysis of water on the alkynyl sulphide.

3.3 Gold-Catalyzed Addition of Sulfonic Acids to Alkynes

3.3.1 Introduction

Based on our successful gold(I)-catalyzed addition of diphenyl phosphates and carboxylic acids to alkynes, we attempted our catalytic system for the addition of sulfonic acids to alkynes. Most of the existing methods follow the sulfonylation of the ketone enolate with sulfonic anhydride by base.\(^{67}\) Like vinyl phosphates, vinyl sulfonates are also used as an important building blocks in organic synthesis, as a electrophiles for cross-coupling reactions.\(^{68}\) Vinyl sulfonates are more stable to water than triflates. In literature it was found that Hirsch et al. demonstrated the addition of methanesulfonic acid to tert-butylacetylene catalyzed by HgO with one example.\(^{69}\)

3.3.2 Results and Discussion

Treatment of 1-decyne with benzenesulfonic acid in the presence of 5 mol % PPh$_3$AuCl and 5 mol % AgPF$_6$ in toluene at room temperature for 12 h afforded a roughly equimolar mixture of $51$ and $52$ in 78% yield. Apparently, the Markovnikov product $51$ was isomerized to the thermodynamically more stable isomer $52$ under the present condition.

\[
\text{Scheme 3.9 Gold(I)-catalyzed addition of benzenesulfonic acid to 1-decyne}
\]
To avoid the isomerization and to get exclusively the Markovnikov addition product under strong acidic conditions, we tried to perform the same reaction in the presence of a base such as triethylamine and Na$_2$CO$_3$. When the reaction was repeated in the presence of 2 equiv triethylamine in toluene, the reaction did not occur to an observable extent, probably due to deactivation of the gold catalyst by triethylamine.

$^a$ used 5 mol % PPh$_3$AuCl and 5 mol % AgPF$_6$ in toluene.

However, when the reaction was performed in the presence of 2 equiv Na$_2$CO$_3$, the reaction proceeded cleanly at room temperature and was completed within 5 h, yielding the desired vinyl sulfonate 51 in 86% yield. Several noteworthy features are apparent. First, the reaction was cleaner and faster. Second, the isomerisation of the Markovnikov product to the thermodynamic isomer did not occur. The use of potassium carbonate was less effective and the desired product was obtained only in 62% yield. Unfortunately, during our studies we realized that the reaction appeared in *Chem. Commun.*, in which a catalytic amount of PPh$_3$AuNO$_3$ and phthalimide were employed in dichloroethane as solvent at 100 °C for 4 h.}$^{70}$

</table>

\(^a\) ratio of Markovnikov and anti-Markovnikov products. \(^b\) heated at 60 °C. \(^c\) ratio of trans and cis isomers.

Compared to their condition, our condition is much milder and faster because the reaction occurs at room temperature with high regioselectivity. The addition of methanesulfonic acid to but-3-ynylbenzene under the standard condition afforded the Markovnikov addition product 51b in 76% yield and the reaction was completed at room temperature for 3 h.

We successfully added sulfonic acids to terminal aliphatic alkynes in presence of gold catalyst. Then we moved to aromatic terminal alkynes with methanesulfonic acid and benzenesulfonic acid. When the methanesulfonic acid was added to phenylacetylene in presence of 5 mol % PPh\(_3\)AuCl and 5 mole % AgPF\(_6\) and 2 equiv of Na\(_2\)CO\(_3\) at room temperature, the reaction was complete in 3 h and afforded the desired Markovnikov product 51c in 67% yield and anti-Markovnikiv product in 3% yield. Treatment of phenylacetylene with benzenesulfonic acid gave the Markovnikov addition product 51d in 77% and the anti-Markovnikov product in 8% yield. In addition, a small amount of acetophenone was observed due to hydrolysis of phenylacetylene under the present condition with methane sulfonic acid, the hydration product was observed in 15% yield.
For instance, methanesulfonic acid underwent a clean addition to ethyl propiolate and phenylpropiolate $51e$ and $51g$ to yield cis-vinyl mesylate in 80% and 90% yield, respectively. Furthermore, methanesulfonic acid underwent addition to propargy alcohol to give the corresponding vinyl sulfonate $51f$ without influence of the hydroxyl group. In the cases of conjugated alkynes having electron-withdrawing groups, the addition was regio- and stereo-specific via trans-addition. Prop-1-ynylbenzene did not react with methanesulfonic acid in the presence of Na$_2$CO$_3$ but reacted very slowly at 60 °C without Na$_2$CO$_3$ to afford $51i$ in 75% yield.

### 3.4 Conclusion

In summary, we developed gold(I)-catalyzed hydroacyloxylation and hydrosulfonyloxylation of carboxylic acids and sulfonic acids to alkynes to provide enol esters and vinyl sulfonates in high yields. The gold(I)-AgPF$_6$ catalyst system provides the Markonikov addition product in good yields while in presence of AgOTf cocatalyst, the Markovnikov addition product underwent isomerization to thermodynamically stable enol benzoate in good yields.
Chapter IV. Transition Metal-Catalyzed C-H Activation of Arenes

4.1 Introduction

Transition metal-catalyzed specific inert C-H bonds functionalization has emerged as a powerful tool in organic synthesis. The development of new C–C and C–heteroatom bond formation is a critical challenge in organic chemistry and, in this regard, C–H bond activation reaction represents one of the most promising approaches in recent years. Activation of arene C-H bonds has been demonstrated using several transition-metals like Pd, Rh and Ru. C-H bond activation processes brought a revolution in production of pharmaceuticals, materials and polymers and are already proven to be valuable in natural product synthesis. Several C-H bond strategies have been exploited in the total synthesis of natural products and Figure 4.1 highlights a list of selected natural products involving C-H activation strategies.

\]
Generally, the directing group strategy has been instrumental in enabling array of metal catalyzed C-H activation reactions during the past several decades. Directing groups usually can be a hetero atom. Directing element coordinates to the metal and brings the metal centre into close proximity of specific C-H bond to form cyclometallated intermediates. As shown in table 4.1, a variety of directing groups have been developed. To develop synthetically useful the C–H bond activation reactions, the desired C–H bond in an organic molecule must be selectively activated over all the C–H bonds present in the molecule. Especially in benzene derivatives, because there is a slight difference in the reactivity between the C–H bonds, a system to control regioselectivity is highly necessary. To overcome uncontrolled site selectivity, a number of examples of C–C and C–heteroatom bond forming reaction have been reported through introduction of a directing group in recent years. Although the use of the directing group has become the practical strategy for allowing selective functionalization, this approach, in most cases, leads to increase reactivity of ortho C–H bond on the arene to the directing group.

In this chapter, we mainly focused on palladium and rhodium-catalyzed C-H arylation and C-H alkenylation.

4.2 Pd and Rh-Catalyzed C-H Arylation of Arenes

Biaryl scaffolds are an important structural motif in natural products, pharmaceuticals and materials. Biaryl motifs can be prepared by using classical cross coupling reactions as well as C-H activation processes. For the green and sustainable, transition metal-catalyzed C-H activation of arenes is the best alternative over the traditional cross coupling reactions.
Scheme 4.1 Arylation of C-H bonds

Chealation assisted C-H arylation of unactivated arenes is regio- and stereo-selective. The directing group is essential for C-H functionalization of unactivated arenes to achieve selectivity and broad substrate scope.

Scheme 4.2 Mechanistic manifolds of Pd-catalyzed C-H functionalization

Mechanistic aspects of palladium catalyzed C-H activation can be explained two pathways. First one is reductive functionalization pathway, in which follows Pd(II)/Pd(0)
catalytic cycle. Functionalization will occur via reductive elimination or β–hydride elimination. The second is oxidative functionalization pathway. Functionalization proceeds with electrophilic reagent. The electrophile can be cleaved via distinct mechanisms which include one-electron oxidation of palladacycle (Pd(II)/Pd(I)), two-electro oxidation of palladacycle (Pd(II)/Pd(III) or Pd(IV)) or without disturbing the oxidation state of metal centre (Scheme 4.2).

In 1992, Dyker reported Pd(II)-catalyzed C-H arylation using 2-Iodoanisole. In 1997, Miura reported regioselective arylation of 2-phenyl phenols and naphthols using Pd(II) catalyst. The treatment of 2-phenyl phenol with aryl iodide in the presence of Pd(OAc)$_2$, 1 equiv of Cs$_2$CO$_3$ at 100 °C in DMF furnished the arylated product (Scheme 4.3).$^{74}$

![Scheme 4.3 Pd(II)-catalyzed C-H arylation](image)

In 2005, Sanford utilized hypervalent iodonium sources like arylidonium tetrafluoroborate and aryl iodonium triflate. Iodonium salts play a dual role as both aryl sources and oxidants. The reactions proceeded faster and high yields were obtained under mild reaction conditions. The reaction mechanism follows Pd(II)/Pd(IV) catalytic pathway (Scheme 4.4).$^{75}$
Daugulis reported Pd-catalyzed C-H arylation using readily available carboxylic acids as substrates. Carboxylate directed ortho-arylation of arenes was accomplished using aryl halides. After that, Yu group demonstrated C-H arylation of benzoic acid using aryltrifluoroborates and organoboron reagents. Furthermore, it was noteworthy that the same group reported for the first time arylation of sp\(^3\) C-H bonds in aliphatic carboxylic acids. When the reaction was carried out aliphatic acids with 2 equiv of aryl iodide in presence of 10 mol % Pd(OAc)\(_2\), 2 equiv of Ag\(_2\)CO\(_3\), 1 equiv K\(_2\)HPO\(_4\), 2 equiv NaOAc in \(t\)-Butanol at 130 °C afforded a mixture of monoarylated and diarylated products in good yields. Low yields were obtained using organoboron reagent instead of aryl iodide (Scheme 4.5).\(^{76}\)

Shi and coworkers described acetanilide assisted Pd-catalyzed C-H arylation using (trialkoxy)phenylsilane as coupling partner. Treatment of acetanilide with trimethoxy phenylsilane in the presence of 5 mol % Pd(OAc)\(_2\), 2 equiv Cu(OTf)\(_2\) and 2 equiv of AgF in 1,4-dioxane under reflux condition furnished mono arylation product in excellent
yields (Scheme 4.6). C-H arylation of acetanilide can also accomplished using aryl boronic acids as arylating agent.\(^77\)

![Scheme 4.6 Ortho arylation of acetanilide C-H bonds](image)

Recently, Dong and coworkers reported C-H arylation of phenylcarbamates with benzene and 1,2- substituted benzenes. Reaction was carried out with 10 mol % Pd(OAc)\(_2\) and sodium persulfate oxidant in excess TFA at 70 °C and afforded the corresponding C-H arylated products (Scheme 4.7).\(^78\)

![Scheme 4.7 Oxidative arylation of phenylcarbamates](image)

In 2008, Booker-Milburn introduced an urea directing group, which is a more active coupling partner in C-H functionalization than other anilides. Lipshutz also utilized this directing group for Pd(II)-catalyzed C-H arylation reaction. Biaryl derivatives were obtained at room temperature using water as solvent (Scheme 4.8).\(^79\)

![Scheme 4.8 C-H arylation of urea in water](image)

More recently, Glorius reported Rh(III)-catalyzed dehydrogenative cross-coupling between benzamides with halogen-substituted benzene derivatives. The treatment of
benzamides with aryl halides using 2.5 mol % (RhCp*Cl₂), 10 mol % AgSbF₆, 2.2 mol % Cu(OAc)₂ oxidant and additives like PivOH, CsOPiv furnished biarylated product in excellent yields. Harsh reaction conditions are required to achieve two fold C-H activation (Scheme 4.9).⁸⁰

\[
\begin{align*}
\text{R} &= \text{Et, iPr} \\
\text{X} &= \text{Cl, Br, I}
\end{align*}
\]

Scheme 4.9 Rh-catalyzed aryl-aryl bond formation

4.2 Pd and Rh-Catalyzed C-H Alkenylation of Arenes

Transition metal catalyzed oxidative Mizoroki-Heck reaction is straight forward reaction in organic chemistry. Pioneering work from Murai showed ortho-directing group assisted C-H olefination using Ru catalyst.⁸¹ After that a milestone work from Fujiwara⁸², a lot of efforts have been made in the arylation of alkenes using Pd, Rh, and Ru.

In 2002, Leeuwen demonstrated C-H olefination of acetanilide under mild reaction conditions. The reaction proceeded at room temperature and afforded the desired olefinated products in good yields (Scheme 4.10).⁸³

\[
\begin{align*}
\text{R} &= \text{Et, iPr} \\
\text{X} &= \text{Cl, Br, I}
\end{align*}
\]

Scheme 4.10 Pd-catalyzed oxidative coupling of anilides with olefins

Recently, Yu group reported carboxylate directed Pd(II)-catalyzed C-H olefination of substituted phenylacetic acid. Treatment of phenylacetic acid with ethylacrylate using 5 mol % Pd(OAc)₂, 1 atm O₂ as terminal oxidant afforded the corresponding alkenylation
product in excellent yields. Benzoquinone used as a ligand for the selective alkenylation. Selectivity is tuned by introducing amino acid derivatives as ligands. This methodology also applied to commercially available drugs NSAIDs (ibuprofen, naproxen, ketoprofen and flubiprofen). Furthermore, C-H alkenylation of benzenesulfonamide using sulfonamide as a directing group explained by the same group (Scheme 4.11).

Scheme 4.11 C-H Olefination of phenylacetic acid and benzenesulfonamides

The same research group extended to sp\textsuperscript{3} C-H bonds. Amide directed Pd(II)-catalyzed C-H olefination of β-C-H bond and subsequent 1,4-conjugate addition gave the corresponding lactum compounds (Scheme 4.12).

Scheme 4.12 Amide directed olefination of sp\textsuperscript{3} C-H bond

More recently, Gevorgyan reported that Pd(II)-catalyzed o-alkenylation using silanol as a temporary directing group. It is noteworthy that the directing group can be easily removed after C-H olefination reaction (Scheme 4.13).
On the other hand, Rh is also known to be suitable in C-H activation reactions. Rhodium was less explored compared to palladium. Specifically rhodium will allow low catalyst loading, high selectivity and broad olefin scope. In 2000, Matsumoto and Yoshida described rhodium-catalyzed oxidative coupling of benzene with ethylene. Last four years, many groups extensively investigated rhodium-catalyzed C-H activation of arenes with alkenes and alkynes.

Glorius reported Rh(III)-catalyzed C-H olefination using directing groups like acetonilide, acetophenone and benzamides. He also demonstrated C-H alkenylation with modified directing group having internal oxidant. In the presence of internal oxidants within the molecule, the C-H olefination occurred regio- and mono-selectively under mild reaction conditions. N-Methoxy benzamides underwent clean monoolefination with a variety of styrene derivatives using 1 mol% of (RhCp*Cl$_2$)$_2$, 30 mol% CsOAc in methanol at 60 °C to afford olefinated benzamides in excellent yields (Scheme 4.14).

**Scheme 4.13** Silanol directed Pd-catalyzed C-H olefination

**Scheme 4.14** Rh(III)-catalyzed C-H olefination using various directing groups
In 2011, Chang developed rhodium-catalyzed olefination using ester as directing group. Thus, treatment of arene esters with acrylates using 2.5 mol % (RhCp*Cl₂)₂, 10 mol % AgSbF₆ and 20 mol % Cu(OAc)₂ in dichloroethane under aerobic condition affords selective olefinated products in good yields (Scheme 4.15).  

![Scheme 4.15](image)

**Scheme 4.15** Ester group directed Rh(III)-catalyzed ortho-olefination

Very recently, Huang and coworkers reported triazene as removable directing group for Rh(III)-catalyzed C-H olefination reaction. Triazene substituted arenes undergo oxidative coupling with varius olefins using 1 mol % (RhCp*Cl₂)₂, 2 equiv of Cu(OAc)₂.H₂O and 30 mol % AgOAc in methanol at 90 °C furnished the corresponding olefinated products in excellent yields (Scheme 4.16).  

![Scheme 4.16](image)

**Scheme 4.16** Triazene directed Rh(III)-catalyzed C-H olefination

Among a wide range of directing groups in C-H activation, ketones, carbamates, and carboxylic esters are less commonly used due to their weak coordinating properties toward metals and may be more challenging directing groups for further development. Furthermore, many directing groups are restricted within pyridines, carboxylic acids, or their derivatives, thus development of new practical directing groups is still a significant issue in the field of straightforward reactions.
Proposed Work

The work of this thesis is directed towards introduction of new phosphoryl directing group in the field of C-H activation. Transition metal-catalyzed C-H bond activation and functionalization is atom economic and emerged as powerful tool in organic synthesis. Organophosphorous compounds are very important in numerous biological functions. Organophosphorous derivatives are already proved in organic chemistry as cross coupling partners. Since there is a remarkable similarity in reactivity and bioactivity between the carbon species and their phosphorus counterparts, we imagined that functionalization of organophosphorous compounds via C-H bond activation would be advantageous over previously reported methods.

The aim of this project is to develop phosphoryl-derived directing groups for selective functionalization. This directing group can be utilized for the functionalization of arenes using C-H activation strategy. We choose aryl phosphoramidates and aryl phosphonates, which are synthetically more useful building blocks in organic chemistry. We envisioned that C-H activation of these organophosphorous derivatives using appropriate transition metal could lead to selective C-H functionalizations and have explored these substrates for Pd and Rh-catalyzed C-H arylation and C-H alkenylation strategies.

Chapter V. Pd-Catalyzed C-H Arylation of Phosphoramidates

5.1 Introduction

Organophosphorus compounds continue to receive widespread attention due to their ubiquity in biological systems. Organophosphonates are essential for human, animal and plant life. They are main building blocks in DNA, RNA, skeletal structure and cell membranes. Organophosphorous compounds are not only used in agrochemicals as insecticides, herbicides and also have potential to serve as novel drugs in pharmaceutical industry. Moreover phosphorous compounds also play a significant role in the field of organic synthesis.

Organophosphorous compounds have attracted considerable interest owing to their broad applications in medicinal chemistry and materials. Particularly, in the field of organic synthesis, organophosphorous derivatives are used as ligands in organic catalysis and organometallic catalysis. Many chiral based phosphorous catalysts developed for enantioselective transformations include phosphinic acid derivatives (Fig. 5.1).

![Figure 5.1 Binol derived monophosphinic acid catalysts for enantioselective transformations](image)

In addition, organophosphorous compounds are also used for the preparation of olefins by the Horner-Wadsworth-Emmons reaction. This approach is very useful for the selective
preparation of trans olefins. The reaction was carried out with the phosphonate stabilized carbanion attack on the corresponding aldehydes or ketones under basic conditions.

Scheme 5.1 Preparation of alkenes from Wittig-Horner reaction

Furthermore, tremendous efforts have been made for cleavage of the C-P bond as well as construction of the C-P bond. Organophosphates already proved several synthetic applications, especially as good electrophiles in the area of transition metal-catalyzed cross coupling reactions. K. Oshima reported palladium catalyzed oxidative Heck reaction using cleavage of aryl phosphinic acids C-P bond.\textsuperscript{108}

Scheme 5.2 Cross coupling reactions of organo phosphorous compounds
5.1.2 Whether an Organo Phosphorous Derivative Serves as Directing Group?

![Scheme 5.3 ortho C-H activation of organophosphates](image)

Organophosphorous compounds are useful in a variety of organic transformations. Now the question is whether phosphoryl oxygen (P=O) can be used as a directing group for the C-H activation process. Since the C-H activation is a hot topic in the field of current organic chemistry, we have been interested in using organophorous derivatives as directing groups for C-H activation processes. To extend the utility of organophosphates and also considering the interest in functionalization of arenes, we contemplated the possibility of P=O directed Pd insertion onto the C-H bond of arenes. Since N-aryl phosphoramidates are utilized as synthetic derivatives for many organic transformations, we chose the phosphoramidate as the model directing group for C-H arylation reactions. As far as we know N-aryl phosphoramidate have not been utilized for the C-H activation reactions.\(^{109}\)

In addition, N-aryl phosphoramidates are among the most prominent synthetic derivatives due to versatile functionalities for further transformations (Scheme 5.4).\(^{110}\) For example, N-aryl phosphoramidates could be used for the preparation of imines 52 by aza-Witting reaction.\(^{110c, g}\) Other applications include synthesis of heterocyclic compounds via stabilized anion of N-aryl phosphoramidates.\(^{110b}\) Recently it was reported that functionalized aziridines 53 were obtained by nucleophile-induced cyclization of readily available anion of N-aryl phosphoramidates.\(^{110b}\) N-Aryl phosphoramidates have also been used to afford 1,2-disubstituted azetidines and 1,2,4-trisubstituted azetidines 54 by means of reactions with Bayliss-Hillman adduct and aza-Michael adduct respectively.\(^{110c, fh}\)
Furthermore, treatment of isatoic anhydride with \(N\)-aryl phosphoramidates yielded various 55 quinazolinedione derivatives.\(^{110g}\)

\begin{center}
\textbf{Scheme 5.4} Various Synthetic Transformations of \(N\)-Aryl Phosphoramidates
\end{center}

Strategy using \(N\)-aryl phosphoramidates as the directing group for C–H bond activation, therefore, represents a relevant example for efficient synthesis of functional molecules which can be transformed into useful building blocks as well.

\section*{5.1 Results and Discussion}

\(N\)-Aryl phosphoramidates can be easily prepared by two different methods using the known procedure. First, treatment of aniline and diethyl phosphite with Idoform in presence of triethylamine in diethyl ether at room temperature afforded phosphoramidates in high yields.\(^{111}\) Second, treatment of aniline with diethyl phosphorochloridate in presence of triethylamine as a base would also furnished the product in high yields.
Most commonly used arylating agents could be aryl halides and benzene boronic acids for the C-H arylation reactions. Recent studies revealed that hypervalent iodine salts of aryliodonium triflates and aryl iodonium tetrafluoroborate proved very effective aryl source to achieve C-H arylation reaction under mild conditions.\textsuperscript{112} Inspired from the report from Liu on palladium(II)-catalyzed arylation of phenol esters with diphenyl iodonium triflate at room temperature,\textsuperscript{113} we studied C-H arylation of N-aryl phosphoramidate using Ph\textsubscript{2}IOTf as the arylating agent. Diphenyl iodonium triflate can also prepared by known procedure.\textsuperscript{114}

\textit{O}-Tolyl phosphoramidate was selected as a model substrate for initial investigation of Pd(II)-catalyzed arylation reaction using Ph\textsubscript{2}IOTf. To begin with, the reaction was carried out at 60 °C using 1,4-dioxane as a solvent for 16 h (Table 5.1). When the reaction was performed in the absence of additives, the reaction did not give any observable amount of desired product (Table 5.1, entry 1). Unfortunately, arylation of 56a did not progress under both basic and solely acidic condition at all and the starting material was remained quantitatively (Table 5.1, entry 2, 4). To elicit the reaction, we extensively tested various additives which were known to positively influence palladium-catalyzed C–H activation reactions. Several additives like Ag\textsubscript{2}CO\textsubscript{3} and Cu(OAc)\textsubscript{2} were tested to be incompatible and AgO, Cu(OTf)\textsubscript{2} gave untidy reaction mixtures with the present reaction conditions (Table 5.1, entry 5, 8, 6 and 9). The use of additives like Na\textsubscript{2}S\textsubscript{2}O\textsubscript{8} was also unsuccessful.
Gratifyingly, we observed that arylation of N-aryl phosphoramidate proceeded in the presence of both catalytic amount of TfOH and 3 equiv of Cu$_2$O in 1,4 dioxane after heating at 60 °C for 16 h to yield the corresponding arylated product 57a in 25% yield (Table 5.1, entry 10).

$^a$5 mol % Pd(OAc)$_2$, 1.2 equiv of Ph$_2$IOTf, 20 mol % of NaOAc, AcOH and TfOH used and 3 equiv of oxidant in 1,4-dioxane for 16 h. $^b$20 mol % Pd(OAc)$_2$ used. $^c$reaction carried out for 3 h. $^d$without Pd catalyst. $^e$20 mol % of CuO used and 69% o-tolyl phosphoramidate recovered.
Encouraged by the result, we tried the reaction with different copper salts to improve the C-H arylation turnover. CuO turned out to be best additive and accomplished C-H arylated product 57a in 78% yield (Table 5.1, entry 13). Prompted by the literature reports on the C-H arylation by copper, we performed the reaction in the absence of Pd(OAc)₂ but found the recovery of the starting material (Table 5.1, entry 15). To push the reaction condition to even lower temperature, we increased the catalyst loading from 5 mol % to 20 mol % of Pd(OAc)₂ but somewhat surprisingly the yield was dropped to 37% and compound 58 was isolated in 29% yield.

The best result was obtained by using 5 mol % of Pd(OAc)₂, 20 mol % of TfOH and 3 equiv of CuO in 1,4-dioxane at room temperature for 3 h (Table 5.1, entry 14). Especially, it was also discovered that reaction carried out at higher temperature provided a slightly lower yield (Table 5.1, entries 12–14). Notably we also observed that a stoichiometric amount of CuO was required to complete the reaction (Table 5.1, entry 14).

Other aryl sources were also screened, like benzene, iodobenzene, phenyl boronic acid under the standard conditions. However, the reaction did not proceed to give the desired product.

$^a$20 mol % Pd(OAc)$_2$ used. $^b$10 mol % Pd(OAc)$_2$ used and 1 equiv of TfOH used.

To establish the optimum condition, we next examined the effect of solvent for this arylation process. As shown in table 5.3, all the solvents examined were ineffective for the arylation. Thus, 1,4-dioxane found out to be the best solvent for this C-H arylation reaction with Ph$_2$IOTf by using phosphoramidate directing group.

Having optimum condition in our hand, the scope of the present method was examined under the standard condition. Arylation of unsubstituted phosphoramidate afforded the desired mono-phenylated product 57b selectively. However, 10 mol % Pd(OAc)$_2$ was required for the completion of the reaction. High selectivity was accomplished in case of phosphoramidate having ortho benzyl group. It was observed that C−H phenylated compound 57c was isolated in 80% yield (Scheme 5.6). C-H arylation of phosphoramidate having electron-donating methyl and methoxy groups at meta position of phenyl ring proceeded smoothly to give the corresponding products 57d and 57f in 86% and 84%, yields respectively (Scheme 5.6). Interestingly, para substituted phosphoramidates equally worked well with mono-phenylation products in excellent
yields. Substrates bearing tert-butyl and methoxy at para position, the C-H arylation proceeded selectively and afforded the corresponding mono arylated products 57e and 57g in 76% and 80% yields (Scheme 5.6).

Scheme 5.6 Synthesis of N-Aryl Phosphoramidates

Furthermore, dimethoxy-substituted N-aryl phosphoramidate underwent clean arylation to obtain C–H phenylated product 57i in 82% yield. In addition, phosphoramidates having both bromo and methyl group also underwent efficient C–H arylation which provided 57j and 57k in 70% and 75% yield. The tolerance of bromo group is especially useful for further functionalization.
With these results in hand, we examined palladium-catalyzed arylation of \( N \)-alkyl-N-aryl phosphoramidates (Scheme 5.7). When \( N \)-alkyl-N-aryl phosphoramidate was subjected to C-H arylation under the standard condition, mono selective ortho phenylated product 60a was accomplished in high yield. The electron-donating groups like methyl and methoxy at para position proceeded smoothly to give the corresponding products 60b and 60d in 75% and 75% yield, respectively (Scheme 5.7).

The phosphoramidates having methoxy at meta position also worked well (60c). \( N \)-aryl-N-methyl phosphoramidates with chloride or bromide as a substituent on the phenyl ring also afforded desired products 60e and 60f in good yields (Scheme 5.7). The presence of halide can be utilized to introduce other functionalities by cross-coupling reactions. Naphthalene derived substrate needed heating 60 °C to furnish 60g in 75% yield. In the same way, 59h also gave the arylated product 60h in 86% yield. These results suggested
that the present methodology can be applied in not only \(N\)-aryl phosphoramidates but also \(N\)-alkyl-\(N\)-phenyl phosphoramidates.

**Scheme 5.8** Arylation of Phosphoramidates using Various Ar\(_2\)IOTf

![Diagram of reaction](image)

Furthermore, we also examined the generality of our methodology for other hypervalent iodine aryl source. Ar\(_2\)IOTf containing electron-donating methyl substituent turned out to be compatible with the Pd-catalyzed C–H arylation of \(N\)-aryl phosphoamidates and \(N\)-alkyl-\(N\)-aryl phosphoramidates. Treatment of \(N\)-alkyl-\(N\)-aryl phosphoramidates with di(4-methylphenyl) iodonium triflate under optimized condition afforded 61b and 61c in 80% and 81% yields respectively (Scheme 5.8). A similar result was obtained with the phosphoramidate having *ortho* ethyl group 61a. Remarkably, electron withdrawing chloride also tolerated on the oxidant to provide 61d in 53% yield together with recovery of the starting material (32%) (Scheme 5.8).
Based on results, the mechanism of this C-H arylation would involve Pd(II)/Pd(IV) catalytic cycle as shown in scheme 5.6. Initial coordination of Pd(II) catalyst to the N-aryl phosphoramidates and the successive C–H insertion would form the six-membered palladacycle 52x. Here diphenyl iodonium triflate serves as arylating agent as well as oxidizing agent. Subsequently, aryl palladacycle(II) 52x might be oxidized to the Pd(IV) species 52y by Ph2IOTf. The specific role of Cu(II) is still unclear and remains to be elucidated. During optimization the reaction needs a stoichiometric amount of CuO to obtain excellent yields. It clearly shows that CuO play a crucial role as a base for regeneration of palladacycle 52x.

5.3 Conclusion

We have developed a novel protocol to effect C–H arylation at room temperature in which the phosphoramidate group was utilized as a directing group for the first time. The present methodology also could be applied in N-alkyl-N-phenyl phosphoramidates. Stoichiometric amount of CuO was essential for efficient Pd(II)-catalysis for arylation of...
phosphoramidates. This transformation offers a new synthetic tool for construction of complex phosphoramidates from simple ones for the diverse synthesis of industrially and medicinally important molecules.
VI. Rhodium(III)-Catalyzed ortho-Olefination of Aryl Phosphonates

6.1 Introduction

Transition metal-catalyzed C-H alkenylation is an atom economical and straight-forward reaction in organic synthesis. Palladium catalysts have been already used to promote arylation of alkenes, in parallel with rhodium also allowed oxidative addition to arenes and heteroarenes. Rhodium-catalyzed ortho-functionalization of arenes have been actively studied in recent years and has proved to be a highly effective for the formation of C-C and C-hetero atom bonds. In achieving ortho C-H activation, directing groups play a vital role to enhance and to control the reaction. Directing groups like carboxylate esters, carbamates, and ketones are less commonly used due to weak coordination towards metal catalysts.

In the previous chapter, we have demonstrated the possibility of insertion of a metal catalyst into C-H bond through weak coordination of P=O bond with a metal catalyst rather than P-OH bond. Concerning P-OH directing group, our group demonstrated Pd(II)-catalyzed ortho-olefination of aryl phosphoric monoacids and benzylic phosphonic monoacids using mono-phosphoric acid.

6.2 Results and Discussion

The palladium-catalyzed oxidative Heck reactions involving N-aryl phosphoramidate as a substrate was futile. Furthermore, our attempts towards Rh(III)-catalyzed ortho-olefination of 62b and 62c were also unsuccessful. We next studied the reaction with arylphosphonates, which are served as important intermediates in organic synthesis. Aryl phosphonates have various applications in medicinal, polymers and materials.
Scheme 6.1 Ortho olefination of 62a, 62b and 62c

Aryl phosphonates can be easily prepared by the palladium-catalyzed cross-coupling reaction of aryl halides with diaryl and dialkyl phosphites. The choice of metals have been explored and expanded to other metals such as Ni and Cu.

Scheme 6.2 Pd-catalyzed preparation of aryl phosphonates

Diethyl o-tolylphosphonate was used as a model substrate for the metal-catalyzed C-H olefination under various conditions (Table 6.1). We studied the possibility of Pd-catalyzed C-H olefination using an aryl phosphonate ester as the directing group. When 64a was treated with 2 equiv of ethyl acrylate using 5 mol % Pd(OAc)$_2$ and 1 equiv of Cu(OAc)$_2$ oxidant in 1,2-dichloroethane at 110 °C for 15 h, the reaction did not proceed (Table 6.1, entry 1). Pd(II)-catalyzed C-H olefination was unsuccessful by changing oxidants and solvents (Table 6.1, entry 2, 3).

Based on recent work on Rh(III)-catalyzed ortho C-H olefination using a carboxylic ester, we next turned our attention to Rh(III)-catalyzed olefination reaction. Poor results were obtained in the absence of additive or oxidant (Table 6.1, entry 5, 6). In addition, Rh(III)-catalyst was necessary for the C-H alkenylation reaction (Table 6.1, entry 4).

\(^a\) Reaction was carried out in presence of O\(_2\); \(^b\) 5 mol % Pd(OAc)\(_2\) was used; \(^c\) without Rh catalyst.

Interestingly, treatment of \(64a\) with 2 equiv of ethyl acrylate in the presence of 2.5 mol % Rh(III)-catalyst and 10 mol % AgSbF\(_6\) together with 1 equiv of Cu(OAc)\(_2\) as an oxidant in 1,4-dioxane at 110 °C for 15 h afforded 28% of the olefinated product \(65a\) (Table 6.1, entry 7). When the reaction was carried out in 1,2-dichloroethane, the yield drastically improved to 85% (Table 6.1, entry 8). Furthermore, the reaction proceeded smoothly with a catalytic amount of 20 mol % Cu(OAc)\(_2\) in the presence of oxygen to furnish the product in 82% yield (Table 6.1, entry 9). Different oxidants were also screened for this reaction. CuO and silver based oxidants like AgOAc and Ag\(_2\)O gave inferior results (Table 6.1, entries 13 - 15). Furthermore, dichloroethane was found out to be the solvent...
of choice. The reaction did not proceed in toluene, acetonitrile (Table 6.1, entries 10 and 11), whereas low yields were obtained in 1,4-dioxane and \(^{1}\text{AmOH}\) with 34% and 28%, respectively (Table 6.1, entry 7, 12).

**Table 6.2** Alkenylation of aryl phosphonates\(^{a}\)

![Chemical structures](image)

Thus, the subsequent reactions were carried out with 20 mol % of Cu(OAc)\(_2\) in the presence of oxygen using Rh(III)-catalyst in 1,2-dichloroethane at 110 °C for 15 h.

Having the optimized condition in our hand, we investigated the scope of various aryl phosphonates for Rh-catalyzed olefination reaction using ethyl acrylate as counterpart and the results are summarized in Table 6.2. Aryl phosphonates bearing different functional groups were olefinated under the standard condition (Table 6.2, entry 65b - 65l). Electron-poor and electron-rich groups like chloro, phenyl, methoxy and methyl were tolerated.
Chapter VI

(65c, 65d, 65e, 65f). The results clearly demonstrate that electronic nature of the substituents on aryl phosphonates play a marginal role in the olefination reaction. 

*Meta*-substituted aryl phosphonates underwent regioselective olefination, which occurred at sterically less hindered position (65h). As expected, for unsubstituted and *para*-substituted phosphonates, the regioselectivity of the mono-olefination was not well-controlled, giving a mixture of mono-olefinated product (65i, 65j) and di-olefinated product (66i, 66j). On the other hand, in case of naphthyl derivatives C-H olefination occurred regioselectively and afforded the corresponding olefination products in good yields (65k, 65l).

To improve the mono-olefination, we modified the structure of aryl phosphonates changing the alkoxy part with bulkier substituents. When a more bulky di-isopropyl phosphonate 64m was subjected to the optimum condition using 1.2 equiv of ethyl acrylate, a mixture of 65m and 66m was obtained in a ratio of 60:15 in favor of 66m (Scheme 6.2).

**Scheme 6.2** Rh(III)-catalyzed C-H olefination of 64m and 64n
We next turned our attention to a phosphonic dialkylamino group. When the reaction was repeated with 64n, di-olefinated product 66n was not observed under the present condition, albeit with recovery of starting material 64n (30%). A similar result was also obtained with 2 equiv of ethyl acrylate. Mono selectivity was observed in case of 64o, 64p, 64q in moderate yields.

Scheme 6.3 Ortho-olefination of diethyl tolylphosphonate

To broaden the scope of the olefination, tolyl phosphonate 64a was treated with several electron-deficient olefins and styrene derivatives (Scheme 6.3). Reaction of vinyl sulfone with tolyl phosphonate under the standard condition furnished the corresponding olefinated product 67c in 78% yield (Scheme 6.3). The olefination of electron-deficient n-butyl and benzyl acrylate proceeded cleanly to give the corresponding products 67a and 67b in 85% and 75% yields, respectively. Similarly, the olefination reaction with styrene derivatives worked equally well to afford the olefinated products 67d, 67e, 67f in moderate yields. However, the reaction failed to give olefinated products with ethyl crotonate and allyl benzene.
The efficiency of the phosphonate directing group in C-H alkenylation was investigated by competitive study between aryl phosphonate 64a and ethyl benzoate 68. When reaction was carried out with 1.2 equiv of ethyl acrylate a 1:2 mixture of 65a and 68a was isolated, the products indicating that the ester directing group was somewhat more effective than the phosphonate group.

**Scheme 6.4** Competitive ortho olefination between 64a and 68

Based on experimental results, a plausible reaction mechanism for the Rh(III)-catalyzed C-H olefination reaction is shown in scheme 6.5. Coordination of highly cationic rhodium species A to phosphoryl oxygen and subsequent cleavage of C-H bond would form a five-membered rhodocycle C. Then olefin insertion gives the seven-membered intermediate D followed by the subsequent β-hydride elimination would provide the olefination product as

**Scheme 6.5** Plausible mechanism for Rh(III)-catalyzed C-H olefination
well as the regeneration of Rh(I) catalyst. Rh(I) is then reoxidised to Rh(III) in the presence of Cu(OAc)$_2$.

6.3 Conclusion

A new and efficient Rh(III)-catalyzed ortho-alkenylation of aryl phosphonates is developed. The phosphonate group is utilized as the directing group in Rh(III)-catalyzed olefination. The present approach feature broad scope of olefins, good functional group tolerance, and high efficiency. Furthermore, the approach could be applied to further functionalization using alkynes, aldehydes, and other reactive functional groups.
Chapter VII. Experimental Section

Supporting information

7.1 General remarks

Reactions were carried out in oven-dried glassware under nitrogen atmosphere. All commercial reagents were used without purification, and all solvents were reaction grade. All reaction mixtures were stirred magnetically and were monitored by thin-layer chromatography using Merck silica gel 60 F_{254} precoated glass plates, which were visualized with UV light and then developed using either iodine or a solution of anisaldehyde. Flash column chromatography was carried out using Merck silica gel 60 (0.040-0.063 mm, 230-400 mesh) and gradient solvent system (EtOAc : n-hexane as a eluant). $^1$H NMR(400MHz) and $^{13}$C NMR spectra were recorded on a ECA 400 MHz and ECA 400SL spectrometer. Deuterated chloroform was used as the solvent, and chemical shift values ($\delta$) are reported in parts per million relative to the residual signals of this solvent ($\delta$ 7.24 for $^1$H and $\delta$ 77.2 for $^{13}$C). Infrared spectra were recorded on a FTIR spectrometer as either a thin film pressed between two sodium chloride plates or as a solid suspended in a potassium bromide disk. High-resolution mass spectra were recorded on a LC/ HRMS mass spectrometer.
7.2.1 Gold (I)-Catalyzed Addition of Diphenyl Phosphate to Alkynes: Isomerization of Kinetic Enol Phosphates to Thermodynamic Isomers

General procedure of Au-catalyzed addition reactions

Oct-1-en-2-yl diphenyl phosphate (17a)\textsuperscript{1}: To a suspension of Ph\textsubscript{3}PAuCl (12.37 mg, 0.025 mmol), AgPF\textsubscript{6} (6.32 mg, 0.025 mmol) and diphenyl phosphate (125.1 mg, 0.5 mmol) in toluene (2 mL) was added 1-octyne (66.12 mg, 0.6 mmol) at room temperature using v-vial. After being stirred for 9 h, the solvent was removed under reduced pressure. The crude product was purified by silica gel column chromatography (EtOAc:hexane = 1:5) to give oct-1-en-2-yl diphenyl phosphate (159 mg, 88\%) as a colorless liquid. \textsuperscript{1}H NMR (400 MHz, CDCl\textsubscript{3}) \(\delta\) 7.37-7.33 (m, 4H), 7.25-7.19 (m, 6H), 4.93 (t, \(J = 2.2\) Hz, 1H), 4.59 (t, \(J = 2.0\) Hz, 1H), 2.19 (t, \(J = 7.6\) Hz, 2H), 1.44 (quint, \(J = 7.4\) Hz, 2H), 1.31-1.19 (m, 6H), 0.87 (t, \(J = 6.9\) Hz, 3H); \textsuperscript{13}C NMR (100 MHz, CDCl\textsubscript{3}) \(\delta\) 155.9 (d, \(J_{cp} = 9.5\) Hz), 150.5 (d, \(J_{cp} = 7\) Hz), 129.8, 125.5, 120.1 (d, \(J_{cp} = 5\) Hz), 98.0 (d, \(J_{cp} = 4\) Hz), 34.3 (d, \(J_{cp} = 5.4\) Hz), 31.5, 28.4, 26.1, 22.5, 14.1; IR (film) 3071, 2931, 2859, 1940, 1864, 1783, 1726, 1659, 1560, 1591,1490, 958, 688 cm\textsuperscript{-1}; HRMS (EI) calcd. for C\textsubscript{20}H\textsubscript{25}O\textsubscript{4}P: \(m/z\) 360.1490 [M\textsuperscript{+}], found: \(m/z\) 360.1488.

General procedure of Pd-catalyzed cross-coupling reactions

Diphenyl (Z)-1-phenyldec-3-en-1-yn-4-yl phosphate (20a): To a suspension of Pd(PPh$_3$)$_4$ (13.86 mg, 0.012 mmol) and CuI (5.71 mg, 0.03 mmol) in 1.4-dioxane (1.5 mL) was added (Z)-1-iodooct-1-en-2-yl diphenyl phosphate (145.8 mg, 0.3 mmol) at room temperature. After 15 min, Et$_3$N (91.07 mg, 0.9 mmol) and phenylacetylene (36.76 mg, 0.36 mmol) was added. After being stirred for 2 h at room temperature, the reaction mixture was quenched with saturated aqueous NaHCO$_3$. The aqueous layer was extracted with ether (3 × 20 mL), dried with MgSO$_4$, filtered, and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (EtOAc:hexane = 1:10) to give 20a (116.0 mg, 84%) as a brown oil. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.30-7.19 (m, 13H), 7.16-7.12 (m, 2H), 5.33 (s, 1H), 2.42 (t, $J = 7.6$ Hz, 2H), 1.49 (quint, $J = 7.5$ Hz, 2H), 1.32-1.20 (m, 6H), 0.87 (t, $J = 6.9$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 159.0 (d, $J_{cp} = 8.8$ Hz), 151.0 (d, $J_{cp} = 7.7$ Hz), 131.9, 130.2, 128.6, 125.8, 123.7, 120.6, 96.7, 96.6, 94.6, 83.6 (d, $J_{cp} = 2.9$ Hz), 34.8, 31.9, 28.9, 26.8, 22.9, 14.5; IR (film) 3061, 2930, 1489, 1188, 1160, 1010, 961, 689 cm$^{-1}$; HRMS (EI) calcd. for C$_{28}$H$_{29}$O$_4$P: m/z 460.1803 [M$^+$], found: m/z 460.1803.

(Z)-1,4-diphenyldec-3-en-1-yn (25a): To a suspension of PdCl$_2$ (1.773 mg, 0.010 mmol) and (Z)-diphenyl 1-phenyldec-3-en-1-yn-4-yl phosphate (92.1 mg, 0.2 mmol) in THF (1.0 mL) was added phenyl magnesium bromide 1.0 M in THF (39.9 mg, 0.22 mmol) at room temperature. After being stirred for 15 min at room temperature, the reaction mixture was,
filtered and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (hexane) to give 25a (37.0 mg, 70%) as a yellowish oil. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.59 (d, $J = 8.0$ Hz, 2H), 7.38 (t, $J = 7.4$ Hz, 2H), 7.33-7.29 (m, 1H), 7.28-7.22 (m, 5H), 5.80 (s, 1H), 2.55(td, $J = 7.5$ Hz, $J = 1.0$ Hz, 2H), 1.43-1.37 (m, 2H), 1.34-1.22 (m, 6H), 0.86 (t, $J = 6.9$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 154.3, 140.0, 131.7, 128.6, 128.5, 128.3, 128.14, 128.11, 124.3, 106.2, 91.5, 89.1, 38.3, 32.0, 29.3, 28.8, 23.0, 14.5; IR (film) 2025, 2855, 1489, 755, 690, 441, 427 cm$^{-1}$; HRMS (EI) calcd. for C$_{22}$H$_{24}$: $m/z$ 288.1878 [M$^+$], found: $m/z$ 288.1880.

Diphenyl (Z)-1-phenyloct-1-en-2-yl phosphate (21a): To a suspension of Pd(PPh$_3$)$_4$ (11.56 mg, 0.010 mmol) in 1.4-dioxane (1.0 mL) was added (Z)-1-iodooct-1-en-2-yl diphenyl phosphate (97.26 mg, 0.2 mmol) at room temperature. After 15 min, Et$_3$N (40.48 mg, 0.4 mmol), 3.0 M K$_3$PO$_4$ (138.6 mg, 0.6 mmol) and phenylboronic acid (29.27 mg, 0.24 mmol) was added. After being stirred for 1 h at 70 °C, the reaction mixture was quenched with saturated aqueous NaHCO$_3$. The aqueous layer was extracted with ether (3 × 20 mL), dried with MgSO$_4$, filtered and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (EtOAc:hexane = 1:10) to give 5a (55.0 mg, 63%) as a brown oil. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.42 (d, $J = 8.4$ Hz, 2H), 7.28 (t, $J = 7.9$ Hz, 4H), 7.22-7.11 (m, 9H), 5.81 (s, 1H), 2.54 (t, $J = 7.5$ Hz, 2H), 1.61 (quint, $J = 7.5$ Hz, 2H), 1.38-1.24 (m, 6H), 0.87 (t, $J = 6.8$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 150.9 (d, $J_{cp} = 6.9$ Hz), 149.3 (d, $J_{cp} = 8.7$ Hz), 134.2, 130.1, 129.2, 128.6, 127.4, 125.7, 120.4 (d, $J_{cp} = 4.9$ Hz), 114.5 (d, $J_{cp} = 8.6$ Hz), 35.4, 32.0, 29.0, 27.4, 22.9, 14.5; IR (film) 2954, 2929, 1591, 1290, 1190, 1010, 776, 402 cm$^{-1}$; HRMS (EI) calcd. for C$_{26}$H$_{29}$O$_4$P: $m/z$ 436.1803 [M$^+$], found: $m/z$ 436.1806.
(Z)-deca-1,3-dien-4-yl diphenyl phosphate (22c): To a suspension of PdCl\(_2\)(PPh\(_3\))\(_2\) (10.52 mg, 0.015 mmol) and (Z)-1-iodooct-1-en-2-yl diphenyl phosphate (145.8 mg, 0.3 mmol) in DMF (1.5 mL) was added tributyl(vinyl)tin (142.6 mg, 0.45 mmol) at room temperature. After being stirred for 16 h at room temperature, the reaction mixture was quenched with saturated aqueous NaHCO\(_3\). The aqueous layer was extracted with ether (3 × 20 mL), dried with MgSO\(_4\), filtered and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (EtOAc:hexane = 1:10) to give 7c (110.0 mg, 95%) as a yellow oil. \(^1\)H NMR (600 MHz, CDCl\(_3\)) \(\delta\) 7.35 (t, \(J = 7.9\) Hz, 4H), 7.25 (d, \(J = 7.9\) Hz, 4H), 7.20 (t, \(J = 7.4\) Hz, 2H), 6.53 (td, \(J = 10.5\) Hz, \(J = 7.1\) Hz, 1H), 5.58 (d, \(J = 10.7\) Hz, 1H), 5.15 (d, \(J = 17.1\) Hz, 1H), 4.97 (d, \(J = 10.4\) Hz, 1H), 2.36 (t, \(J = 7.5\) Hz, 2H), 1.47 (quint, \(J = 7.5\) Hz, 2H), 1.28-1.20 (m, 6H), 0.86 (t, \(J = 7.1\) Hz, 3H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \(\delta\) 151.0 (d, \(J_{cp} = 7.6\) Hz), 149.6 (d, \(J_{cp} = 9.4\) Hz), 130.2, 130.0, 125.9, 120.6 (d, \(J_{cp} = 4.9\) Hz), 117.3, 116.3 (d, \(J_{cp} = 7.9\) Hz), 34.6, 31.9, 29.0, 26.9, 22.9, 14.4; IR (film) 2956, 2929, 2857, 1490, 1188, 1009, 955, 632 cm\(^{-1}\); HRMS (EI) calcd. for C\(_{22}\)H\(_{27}\)O\(_4\)P: \(m/z\) 386.1647 [M\(^+\)], found: \(m/z\) 386.1646.

(Z)-1-iodohex-1-en-2-yl diphenyl phosphate (19b): \(^1\)H NMR (400 MHz, CDCl\(_3\)) \(\delta\) 7.37-7.18 (m, 10H), 5.64 (s, 1H), 2.49 (t, \(J = 7.8\) Hz, 2H), 1.49-1.43 (m, 2H), 1.31-1.25 (m, 2H), 0.85 (t, \(J = 6.2\) Hz, 3H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \(\delta\) 157 (d, \(J_{cp} = 6.7\) Hz), 150.6 (d, \(J_{cp} = 7.7\) Hz), 129.9, 125.8, 120.4 (d, \(J_{cp} = 4.8\) Hz), 62.1 (d, \(J_{cp} = 11.5\) Hz), 34.9, 28.7, 22.0, 13.8; IR (film) 3012, 2958, 2931, 1637, 1591, 1489, 1296, 1188, 1122, 966; HRMS (EI) calcd for C\(_{18}\)H\(_{20}\)IO\(_4\)P: \(m/z\) 459.0222 [M\(^+\)], found: \(m/z\) 459.0218.
(Z)-1-bromodec-1-en-2-yl diphenyl phosphate (19c): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.37-7.19 (m, 10H), 5.66 (s, 1H), 2.38 (t, $J = 7.6$ Hz, 2H), 1.47-1.44 (m, 2H), 1.27-1.22 (m, 10H), 0.87 (t, $J = 6.9$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 152.5, 150.6, 129.9, 125.7 (d, $J_{cp} = 10.5$ Hz), 120.4, 91.79, 34.4, 32.0, 29.3, 28.9, 26.4, 22.8, 14.3; IR (film) 3018, 2927, 2856, 1653, 1591, 1489, 1296, 1215, 1188, 1139, 1010, 968, 756, 667 cm$^{-1}$; HRMS (EI) calcd for C$_{22}$H$_{28}$BrO$_4$P: m/z 467.0987 [M$^+$], found: m/z 467.0981.

(Z)-2-iodo-1-phenylvinyl diphenyl phosphate (19d): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.49-7.47 (m, 2H), 7.35-7.25 (m, 7H), 7.18-7.13 (m, 6H), 6.38 (s, 1H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 155.0 (d, $J_{cp} = 8.6$ Hz), 150.6 (d, $J_{cp} = 7.7$ Hz), 133.9, 129.9 (d, $J_{cp} = 13.4$ Hz), 128.6, 125.6, 120.3 (d, $J_{cp} = 4.8$ Hz), 66.4 (d, $J_{cp} = 9.6$ Hz); IR (film) 3018, 1591, 1489, 1298, 1215, 1188, 1053, 1024, 966, 756 cm$^{-1}$; HRMS (EI) calcd for C$_{20}$H$_{16}$IO$_4$P: m/z 477.9831 [M$^+$], found: m/z 477.9834.

(Z)-1-(4-bromophenyl)-2-iodovinyl diphenyl phosphate (19e): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.43-7.41 (m, 2H), 7.34-7.19 (m, 6H), 7.18-7.16 (m, 6H), 6.42 (s, 1H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 154.0 (d, $J_{cp} = 8.6$ Hz), 150.5 (d, $J_{cp} = 7.6$ Hz), 132.9, 131.9, 129.9, 128.0, 125.8, 124.2, 120.3 (d, $J_{cp} = 4.8$ Hz), 67.2 (d, $J_{cp} = 9.5$ Hz); IR (film) 3068, 3014, 1589, 1487, 1394, 1307, 1215, 1188, 1043, 947, 754 cm$^{-1}$; HRMS (EI) calcd for C$_{20}$H$_{15}$IO$_4$PBrNa: m/z 578.8834 [M$^+$], found: m/z 578.8836.
(Z)-1-iodo-4-phenylbut-1-en-2-yl diphenyl phosphate (19f): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.38-7.30 (m, 8H), 7.28-7.17 (m, 5H), 7.10 (d, $J = 6.9$ Hz, 2H), 5.63 (s, 1H), 2.82 (s, 4H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 155.7 (d, $J_{cp} = 7.1$ Hz), 150.4 (d, $J_{cp} = 7.6$ Hz), 139.9, 129.9, 128.5, 128.4, 126.3, 125.7, 120.3 (d, $J_{cp} = 4.8$ Hz), 63.1 (d, $J_{cp} = 10.5$ Hz), 37.0, 32.9; IR (film) 3075, 1590, 1488, 1297, 1185, 960, 688, 639 cm$^{-1}$; HRMS (EI) calcd. for C$_{22}$H$_{20}$IO$_4$P: $m/z$ 506.0144 [M$^+$], found: $m/z$ 506.0145.

(Z)-3-(diphenoxophosphoryloxy)-4-iodobut-3-enyl ethyl carbonate (19g): $^1$H NMR (400 MHz, CDCl$_3$) 7.37-7.19 (m, 10H), 5.85 (s, 1H), 4.24-4.15 (m, 4H), 2.90-2.89 (m, 2H), 1.31-1.26 (m, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 154.9, 152.4 (d, $J_{cp} = 7.6$ Hz), 150.4 (d, $J_{cp} = 7.6$ Hz), 130.0, 125.9, 120.4 (d, $J_{cp} = 4.8$ Hz), 65.2, 64.4, 63.5, 34.7, 14.4; IR (film) 3076, 2981, 1735, 1641, 1589, 1487, 1384, 1367, 1184, 1120, 1070, 763, 638 cm$^{-1}$; HRMS (EI) calcd for C$_{19}$H$_{20}$IO$_7$P: $m/z$ 519.0070 [M$^+$], found: $m/z$ 519.0071.

(Z)-4-(benzoyloxy)-1-bromobut-1-en-2-yl diphenyl phosphate (19h): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 8.01-7.98 (m, 2H), 7.45-7.19 (m, 15H), 5.85 (s, 1H), 4.39 (t, $J = 6.6$ Hz, 2H), 2.89-2.86 (m, 2H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 166.7, 151.0, 148.1, 133.3, 130.0, 128.5, 125.9, 120.2, 94.1, 60.6, 33.9; IR (film) 3070, 2962, 1732, 1678, 1589, 1487, 1454, 1382, 1070, 773, 711 cm$^{-1}$; HRMS (EI) calcd for C$_{23}$H$_{21}$O$_6$BrP: $m/z$ 503.0259 [M$^+$], found: $m/z$ 503.0255.
Diphenyl (Z)-1-phenylct-3-en-1-yn-4-yl phosphate (20b): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.34-7.14 (m, 15H), 5.34 (s, 1H), 2.43 (t, $J = 7.8$ Hz, 2H), 1.49-1.45 (m, 2H), 1.35-1.29 (m, 2H), 0.87 (t, $J = 7.3$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 158.6, 150.8, 131.7, 129.9, 128.3, 125.6, 120.4 (d, $J_{cp} = 4.8$ Hz), 96.4, 94.9, 84.1, 34.2, 28.7, 22.2, 13.9; IR (film) 3053, 2958, 2872, 1653, 1591, 1489, 1296, 1265, 1219, 1188, 1161, 1008, 688 cm$^{-1}$; HRMS (EI) calcd for C$_{26}$H$_{25}$O$_4$P: m/z 433.1569 [M$^+$], found: m/z 433.1566.

(Z)-1-(4-bromophenyl)oct-3-en-1-yn-4-yl diphenyl phosphate (20c): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.35-7.09 (m, 14H), 5.31 (s, 1H), 2.40 (t, $J = 7.8$ Hz, 2H), 1.49-1.45 (m, 2H), 1.34-1.28 (m, 2H), 0.87 (t, $J = 7.3$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 159.1, 150.6, 133.1, 131.6, 129.9, 125.7, 122.4 (d, $J_{cp} = 14.4$ Hz), 96.3 (d, $J_{cp} = 7.7$ Hz), 93.2, 84.5, 34.3, 28.6, 22.1, 13.9; IR (film) 3018, 2399, 1591, 1489, 1294, 1215, 1161, 1010, 966, 767, 669 cm$^{-1}$; HRMS (EI) calcd for C$_{26}$H$_{25}$O$_4$PBr: m/z 511.0674 [M$^+$], found: m/z 511.0668.

(Z)-1-(4-methoxyphenyl)oct-3-en-1-yn-4-yl diphenyl phosphate (20d): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.31-7.12 (m, 12H), 6.76-6.73 (m, 2H), 5.32 (s, 1H), 3.77 (s, 3H), 2.43 (t, $J = 7.3$ Hz, 2H), 1.49-1.43 (m, 2H), 1.33-1.28 (m, 2H), 0.86 (t, $J = 7.3$ Hz, 3H); $^{13}$C
NMR (100 MHz, CDCl₃) δ 159.7, 157.9 (d, J= 9.6 Hz), 150.7 (d, J= 7.7 Hz), 133.1, 129.9, 125.6, 120.3 (d, J= 4.8 Hz), 115.6, 113.9, 96.6 (d, J= 8.6 Hz), 82.0, 55.4, 34.2, 28.7, 22.1, 13.9; IR (film) 3016, 2960, 2399, 1602, 1508, 1489, 1292, 1247, 1215, 1026, 966, 771, 667 cm⁻¹; HRMS (EI) calcd for C₂₇H₂₈O₅P: m/z 463.1674 [M⁺], found: m/z 463.1666.

Diphenyl (Z)-1,4-diphenylbut-1-en-3-ynyl phosphate (20e): ¹H NMR (400 MHz, CDCl₃) δ 7.57-7.55 (m, 2H), 7.36-7.55 (m, 18H), 6.08 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 154.5, 150.7 (d, J= 7.7 Hz), 133.6, 131.8, 129.9, 128.7, 128.3, 125.6 (d, J= 16.3 Hz), 120.3 (d, J= 4.8 Hz), 97.7 (d, J= 8.6 Hz), 84.2; IR (film) 3016, 2399, 1593, 1489, 1294, 1215, 1070, 1010, 966, 771, 669 cm⁻¹; HRMS (EI) calcd for C₂₈H₂₂O₄P: m/z 453.1256 [M⁺], found: m/z 453.1262.

Diphenyl (Z)-1,5-diphenylpent-1-en-3-ynyl phosphate (20f): ¹H NMR (400 MHz, CDCl₃) δ 7.52-7.50 (m, 2H), 7.33-7.12 (m, 18H), 5.88 (s, 1H), 3.58 (s, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 155.0, 150.8 (d, J= 7.6 Hz), 136.5, 133.8, 129.8 (d, J= 4.8 Hz), 128.7 (d, J= 5.7 Hz), 120.3 (d, J= 5.7 Hz), 98.1 (d, J= 6.7 Hz), 96.4, 26.2; IR (film) 3053, 2985, 2252, 1489, 1421, 1265, 1219, 910, 771, 650 cm⁻¹; HRMS (EI) calcd for C₂₉H₂₄O₄P: m/z 467.1412 [M⁺], found: m/z 467.1418.
Diphenyl (Z)-1-phenyldodec-5-en-3-yn-6-yl phosphate (20g): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.35-7.24 (m, 10H), 7.18 (t, $J = 6.8$ Hz, 3H), 7.12 (d, $J = 7.1$ Hz, 2H), 5.09 (s, 1H), 2.70 (t, $J = 7.8$ Hz, 2H), 2.43 (t, $J = 7.2$ Hz, 2H), 2.32 (t, $J = 7.6$ Hz, 2H), 1.43 (quint, $J = 7.0$ Hz, 2H), 1.30-1.17 (m, 6H), 0.86 (t, $J = 7.0$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 157.6 (d, $J_{cp} = 9.5$ Hz), 150.6 (d, $J_{cp} = 7.5$ Hz), 140.7, 129.8 (d, $J_{cp} = 8.3$ Hz), 128.3 (d, $J_{cp} = 2.7$ Hz), 126.2, 125.4, 120.2 (d, $J_{cp} = 4.9$ Hz), 96.5 (d, $J_{cp} = 7.8$ Hz), 94.7, 74.4, 35.0, 34.2, 31.4, 28.5, 26.3, 22.5, 21.7, 14.0; IR (film) 2953, 2928, 1591, 1490, 1010, 961, 774, 415 cm$^{-1}$; HRMS (EI) calcd. for C$_{30}$H$_{33}$O$_4$P: $m/z$ 488.2116 [M$^+$], found: $m/z$ 488.2115.

(Z)-1,4-diphenyloct-3-en-1-yne (25b): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.61-7.59 (m, 2H), 7.40-7.22 (m, 8H), 5.80 (s, 1H), 2.56 (t, $J = 7.5$ Hz, 2H), 1.42-1.26 (m, 4H), 0.88 (t, $J = 7.1$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 154.0, 139.7, 131.4, 128.4, 128.3, 128.0, 127.9, 124.1, 106.0, 91.3, 88.9, 37.8, 30.7, 22.5, 14.1; IR (film) 3078, 3014, 2956, 2194, 1591, 1489, 1440, 1377, 1215, 1068, 914, 839, 767, 690 cm$^{-1}$; HRMS (EI) calcd for C$_{20}$H$_{20}$: $m/z$ 261.1643 [M$^+$], found: $m/z$ 261.1653.

1,1,4-triphenylbut-1-en-3-yne (25c): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.60-7.00 (m, 15H), 6.23 (s, 1H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 152.9, 141.6, 139.4, 131.6, 130.4, 128.7,

1-methoxy-4-((Z)-4-phenyloct-3-en-1-ynyl)benzene (22d): \(^1\)H NMR (400MHz, CDCl\(_3\)) \(\delta\) 7.60-7.58 (m, 2H), 7.39-7.19 (m, 6H), 6.79-6.77 (m, 2H), 5.77 (s, 1H), 3.77 (s, 3H), 2.54 (t, \(J = 7.5\) Hz, 2H), 1.38-1.26 (m, 4H), 0.88 (t, \(J = 7.1\) Hz, 3H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \(\delta\) 159.4, 152.9, 139.9, 132.9, 128.3, 128.0, 127.8, 116.3, 114.1, 106.2, 91.5, 87.5, 55.5, 37.7, 30.8, 22.5, 14.1; IR (film) 3012, 2956, 1604, 1508, 1463, 1247, 1170, 1035, 831, 756, 667 cm\(^{-1}\); HRMS (EI) calcd for C\(_{21}\)H\(_{23}\)O: \(m/z\) 291.1749 [M\(^+\)], found: \(m/z\) 291.1752.

Diphenyl (Z)-1-phenylhex-1-en-2-yl phosphate (21b): \(^1\)H NMR (400 MHz, CDCl\(_3\)) \(\delta\) 7.42-7.39 (m, 2H), 7.29-6.78 (m, 13H), 5.81 (s, 1H), 2.54 (t, \(J = 7.3\) Hz, 2H), 1.61-1.57 (m, 2H), 1.39-1.33 (m, 2H), 0.89 (t, \(J = 7.3\) Hz, 3H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \(\delta\) 156.4, 150.6 (d, \(J_{cp} = 7.7\) Hz), 149.0 (d, \(J_{cp} = 8.6\) Hz), 133.9, 129.9, 129.6, 129.0, 128.4, 127.2, 125.6, 120.2 (d, \(J_{cp} = 4.8\) Hz), 115.5, 114.4 (d, \(J_{cp} = 8.6\) Hz), 34.9, 29.3, 22.2, 14.0; IR (film) 3059, 2956, 2870, 1672, 1591, 1489, 1296, 1188, 1095, 960, 754, 688 cm\(^{-1}\); HRMS (EI) calcd for C\(_{24}\)H\(_{25}\)O\(_3\)P: \(m/z\) 409.1569 [M\(^+\)], found: \(m/z\) 409.1563.
(Z)-1,2-diphenyloct-1-ene (23a): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$7.59 (d, $J = 7.5$ Hz, 1H), 7.44 (t, $J = 7.5$ Hz, 1H), 7.36-7.21 (m, 3H), 7.14 (d, $J = 6.6$ Hz, 2H), 7.09-7.01 (m, 2H), 6.91 (d, $J = 6.5$ Hz, 1H), 6.42 (s, 1H), 2.48 (t, $J = 7.2$ Hz, 2H), 1.50-1.21 (m, 8H), 0.87 (t, $J = 6.8$ Hz, 3H); $^{13}$C NMR (400 MHz, CDCl$_3$) $\delta$ 144.0, 141.9, 138.0, 129.4, 129.0, 128.9, 128.2, 127.6, 127.2, 126.4, 41.2, 32.1, 29.3, 28.3, 23.1, 14.5; IR (film) 2928, 1593, 1439, 1187, 962, 693, 541 cm$^{-1}$; HRMS (EI) calcd. for C$_{20}$H$_{24}$: m/z 264.1878 [M$^+$], found: m/z 264.1874.

(Z)-1,2-diphenylhex-1-ene (23b): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$7.39 (d, $J = 7.3$ Hz, 1H), 7.42 (t, $J = 7.8$ Hz, 1H), 7.30-7.04 (m, 6H), 6.90 (d, $J = 6.4$ Hz, 2H), 6.43 (s, 1H), 2.49 (t, $J = 6.7$ Hz, 2H), 1.41-1.25 (m, 4H), 0.88 (t, $J = 7.2$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 143.6, 141.6, 137.5, 129.0, 128.8, 128.6, 127.9, 126.8, 126.1, 40.5, 30.2, 22.4, 14.0, 139.7, 131.4, 128.4, 128.3, 128.0, 127.9, 124.1, 106.0, 91.3, 88.9, 37.8, 30.7, 22.5, 14.1; IR (film) 3153, 2958, 2252, 1791, 1548, 1379, 1219, 906, 732, 650 cm$^{-1}$; HRMS (EI) calcd for C$_{18}$H$_{20}$Na: m/z 259.1463 [M$^+$], found: m/z 259.1466.

(Z)-octa-1,3-dien-4-yl diphenyl phosphate (22a): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$7.36-7.17 (m, 10H), 6.57-6.48 (m, 1H), 5.57 (d, $J = 11$ Hz, 1H), 5.15 (d, $J = 17.4$ Hz, 1H), 4.96 (d, $J = 10.5$ Hz, 1H), 2.36 (t, $J = 7.3$ Hz), 1.49-1.42 (m, 2H), 1.34-1.22 (m, 2H), 0.86 (t, $J = 7.6$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 150.7 (d, $J_{cp} = 7.7$ Hz), 149.4, 129.9, 129.8, 125.7, 120.4, 120.3, 117.1, 116.1 (d, $J_{cp} = 7.7$ Hz), 34.0, 28.8, 22.2, 13.9; IR (film) 2956, 2929, 1668, 1591, 1489, 1417, 1290, 1217, 1188, 960, 771, 688 cm$^{-1}$; HRMS (EI) calcd for C$_{20}$H$_{23}$O$_4$PNa: m/z 381.1232 [M$^+$], found: m/z 381.1235.
Diphenyl (Z)-1-phenylbuta-1,3-dienyl phosphate (22b): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.54-7.51 (m, 2H), 7.34-7.11 (m, 13H), 6.86-6.35 (m, 1H), 6.33 (d, $J = 1.8$ Hz, 1H), 5.38 (d, $J = 17.4$ Hz, 1H), 5.19 (d, $J = 10.5$ Hz, 1H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 150.7 (d, $J = 6.7$ Hz), 145.9, 134.5, 130.3, 129.9, 129.1, 128.6, 125.7 (d, $J = 10.5$ Hz), 120.3 (d, $J = 4.8$ Hz), 117.6 (d, $J = 6.7$ Hz); IR (film) 3043, 2926, 1732, 1643, 1591, 1487, 1456, 1415, 1296, 1217, 1045, 769, 688, 648 cm$^{-1}$; HRMS (EI) calcd for C$_{22}$H$_{19}$O$_4$P: $m/z$ 379.1099 [M$^+$], found: $m/z$ 379.1105.

1-((Z)-octa-1,3-dien-4-yl)benzene (24a): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.37-7.18 (m, 5H), 6.38-6.28 (m, 1H), 6.12 (d, $J = 11.4$ Hz, 1H), 5.16 (d, $J = 17.4$ Hz, 1H), 4.94 (d, $J = 10.4$ Hz, 1H), 2.42 (t, $J = 7.1$ Hz, 2H), 1.34-1.25 (m, 4H), 0.88 (t, $J = 7.3$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 144.7, 140.9, 134.8, 128.8, 128.4, 127.4, 127.0, 126.8, 116.1, 39.0, 30.5, 22.5, 14.1; IR (film) 2925, 1642, 1415, 1217, 961, 769, 688, 647 cm$^{-1}$; HRMS (EI) calcd for C$_{14}$H$_{18}$: $m/z$ 187.1490 [M$^+$], found: $m/z$ 187.1490.

1-((Z)-deca-1,3-dien-4-yl)benzene (24b): $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.36-7.16 (m, 5H), 6.37-6.28 (m, 1H), 6.12 (d, $J = 10.9$ Hz, 1H), 5.18 (dd, $J = 16.9$ Hz, $J = 1.9$ Hz , 1H), 4.94 (dd, $J = 10.1$ Hz, $J = 1.9$ Hz , 1H), 2.41 (t, $J = 7.1$ Hz , 2H), 1.52-1.21 (m, 8H), 0.85 (t, $J = 6.9$ Hz, 3H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 144.6, 140.8, 134.6, 128.6, 128.0,
127.2, 126.8, 115.9, 39.1, 31.7, 28.9, 28.1, 22.6, 14.1; IR (film) 3061, 3034, 2926, 1477, 1429, 1005, 725, 693 cm$^{-1}$; HRMS (EI) calcd. for C$_{16}$H$_{22}$: m/z 214.1722 [M$^+$], found: m/z 214.1722.

7.2.3 Intramolecular Addition of Diphenyl Phosphate to Alkynes

**General procedure for alkynyl hydrogen phosphates**

Phenyl phosphorodichloridate (665 mg, 0.47 mL, 3.15 mmol) was stirred in THF (2 mL) at 0 °C under nitrogen. A solution of alkynyl alcohol (3.00 mmol) in THF (2 mL) was added dropwise by syringe over 0.5 h and then a solution of triethylamine (364 mg, 0.50 mL, 3.60 mmol) in THF (2 mL) was also added dropwise to the reaction mixture for another 0.5 h. The white reaction mixture was then stirred for an additional 3 h at 0 °C and then warmed to room temperature for 1 h. Water (1 mL) was subsequently added dropwise over 10 min and the resultant reaction mixture was left to stir for an additional 3 h at room temperature. The resulting mixture was concentrated to remove the THF before extracting with CH$_2$Cl$_2$ (3x20 mL). The combined organic extracts were dried over anhydrous MgSO$_4$ and concentrated under reduced pressure to afford the crude material, which was then purified by silica-gel chromatography (MeOH/CH$_2$Cl$_2$, 1:9).

**General procedure for the cyclization of alkynyl hydrogen phosphates**

Chlorotriphenylphosphine gold(I) (5 mol%) and silver trifluoromethanesulfonate (5 mol%) were stirred in CH$_2$Cl$_2$ (1 mL) at room temperature under a nitrogen atmosphere. A solution of the alkynyl hydrogen phosphate (0.30 mmol) in CH$_2$Cl$_2$ (2 mL) was added. The reaction mixture was then allowed to stir for 0.5 h before extracting with CH$_2$Cl$_2$ (3x20 mL). The combined organic phases were dried over anhydrous MgSO$_4$, filtered,
and concentrated under reduced pressure to afford the crude material, which was then
purified by silica-gel chromatography (EtOAc/hexane, 3:7)

Phenyl prop-2-ynyl hydrogen phosphate (29a): \(^1\)H NMR (400 MHz, CDCl\(_3\)) \(\delta\) 2.55
(1H, t, \(J = 2.4\) Hz), 4.68 (2H, dd, \(J = 10.1, 2.2\) Hz), 7.16 -7.34 (5H, m), 8.32 (1H, bs); \(^{13}\)C

4-phenylpent-4-en-1-ol (36b): $^1$H NMR (400 MHz, CDCl$_3$): δ 1.59 (br, 1H), 1.67-1.73 (m, 2H), 2.57 (t, 2H, $J = 6.5$ Hz), 5.09 (d, 2H, $J = 1.3$ Hz), 5.29 (d, 2H, $J = 1.3$ Hz), 7.26-7.33 (m, 3H), 7.35-7.43 (m, 2H); $^{13}$C{1H} NMR (100 MHz, CDCl$_3$) δ 31.1, 31.5, 62.3, 112.5, 126.1, 127.3, 128.2, 140.9, 147.9;

7.2.4 Typical procedure for Ph$_3$PAuCl/AgPF$_6$-catalyzed addition of carboxylic acids to alkynes. To a suspension of Ph$_3$PAuCl (10 mg, 0.02 mmol), AgPF$_6$ (5.1 mg, 0.02 mmol) and benzoic acid (50 mg, 0.41 mmol) in toluene (1 mL) was added 1-hexyne (56 µl, 0.49 mmol) at room temperature. After being stirred at 60 °C for 15 h, the solvent was
removed under reduced pressure and the reaction mixture was purified by silica gel column chromatography (EtOAc:hexane = 1:10) to give the title compound.

Typical procedure for the hydroacyloxylation using Ph₃PAuCl/AgOTf catalyst. To a suspension of Ph₃PAuCl (6.1 mg, 0.01 mmol), AgOTf (3.1 mg, 0.01 mmol) and benzoic acid (30 mg, 0.24 mmol) in toluene (1 mL) was added 1-hexyne (34µl, 0.29 mmol) at room temperature. After being stirred for 15 h, the solvent was evaporated under reduced pressure and the resulting crude product was separated by silica gel column chromatography (EtOAc:hexane = 1:10) to give hex-2-en-2-yl benzoate (diastereomeric ratio 1:3.1, 44 mg, 87%) as a colorless oil.

4-((methylsulfonyl)oxy)pent-4-ene-1-yl benzoate (51h): 1H NMR (400 MHz, CDCl3): δ 8.05-8.03 (m, 2H), 7.58-7.43 (m, 3H), 5.08 (s, 1H), 4.87 (s, 3H), 4.37 (t, J = 6.4 Hz, 2H), 3.13 (s, 3H), 2.49 (t, J = 7.6 Hz, 2H), 2.07-2.01 (m, 2H); 13C NMR (100 MHz, CDCl3): δ 166.7, 154.8, 133.2, 130.3, 129.7, 128.6, 102.9, 63.7, 38.1, 31.2, 25.7; HRMS (EI) calcd for C13H16O5S(M+) 285.0797, found 285.0799.

(E)-1-phenylprop-1-en-1-yl methanesulfonate (51i): 1H NMR (400 MHz, CDCl3): δ 7.41-7.24 (m, 5H), 5.84-5.80 (m, 2H), 2.87 (s, 3H), 1.85 (d, J = 6.9 Hz, 3H); 13C NMR (100 MHz, CDCl3): δ 147.0, 134.9, 132.8, 129.3, 128.9, 128.8, 125.7, 117.9, 39.6, 29.8, 12.7; HRMS (EI) calcd for C9H12O3S(M+) 201.0585, found 201.0588.

(E)-1,2-diphenylvinyl methanesulfonate (51j): 1H NMR (400 MHz, CDCl3): δ 7.46-7.34 (m, 3H), 7.19-7.14 (m, 2H), 6.80 (s, 1H), 2.89 (s, 3H); 13C NMR (100 MHz, CDCl3): δ 146.7, 133.5, 129.9, 129.6, 129.2, 129.0, 128.5, 128.1, 123.2, 39.3; HRMS (EI) calcd for C15H14O3S(M+) 275.0742, found 275.0743.

7.2.5 Pd-Catalyzed C-H Arylation of Phosphoramidates
**General procedure:** To an oven dried test tube were added palladium(II) acetate (3.4 mg, 5 mol %), copper(II) oxide (71.6 mg, 0.9 mmol) and diphenyliodonium trifluoromethanesulfonate (154.9 mg, 0.36 mmol) under nitrogen atmosphere. Diethyl arylphosphoramidate (0.3 mmol) in 1,4-dioxane (1.2 mL) was added to the reaction mixture. After being stirred for 5 min, trifluoromethanesulfonic acid (5.3 μL, 20 mol %) was added to the reaction mixture. The reaction mixture was stirred at room temperature. The reaction mixture was quenched with H2O and then, aqueous layer was extracted with dichloromethane (3 x 20 mL). The combined organic phases were washed with NaHCO3 (sat. aq.), dried with MgSO4, filtered and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

[Chemical structure image]

**Diethyl 4’-chloro-3-ethylbiphenyl-2-ylphosphoramidate (61d):** pale brown solid; m.p = 155.2-158.8 °C; $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.40-7.34 (m, 4H), 7.25 (d, J = 1.48 Hz, 1H), 7.20 (td, J = 7.6 Hz, 1.2 Hz, 1H), 7.08 (d, J = 7.2 Hz, 1H), 4.20 (d, J = 4.4 Hz, 1H), 3.87-3.77 (m, 2H), 3.71-3.61 (m, 2H), 2.88 (q, J = 7.5 Hz, 2H), 1.28 (t, J = 7.5 Hz, 3H), 1.14 (td, J = 7.1 Hz, 0.8 Hz, 6H); $^{13}$C NMR (100 MHz, CDCl$_3$) $\delta$ 141.7 (d, $J_{c-p}$ = 3.0 Hz), 139.2, 139.0 (d, $J_{c-p}$ = 4.0 Hz), 131.2, 128.6 (d, $J_{c-p}$ = 2.0 Hz), 128.4, 128.2, 126.2 (d, $J_{c-p}$ = 2.0 Hz), 62.6 (d, $J_{c-p}$ = 6.0 Hz), 24.7, 16.1 (d, $J_{c-p}$ = 7.0 Hz), 14.5; $^{31}$P NMR (162 MHz, CDCl$_3$) $\delta$ 3.47; IR (film) 3082, 2977, 2817, 1229, 1059, 1032, 963, 798; HRMS (EI) calcd. for C$_{18}$H$_{23}$ClNO$_3$P(M$^+$) 367.1104, found 367.1105.
7.2.6 General experimental procedure for the preparation of Aryl Phosphonate (64):\(^6\)

To a stirred solution of diethyl phosphite (2.0 mmol) and triethylamine (2.0 mmol) in presence of a catalytic amount of Pd(PPh\(_3\))\(_4\) (0.08 mmol, 5 mol % equiv), aryl bromide or aryl iodide (1.6 mmol) was added under nitrogen, and the reaction mixture was stirred at 90 °C for 6-15 h. when the aryl halide used was solid, toluene (1 ml) was added as solvent. After the addition of ether, the reaction mixture was filtered. The residue obtained upon evaporation is purified by silica gel column chromatography.

**General experimental procedure for the Rh-catalyzed C-H alkenylation (65):**

(RhCp*Cl\(_2\))\(_2\) (3.4 mg, 0.005 mmol, 2.5mol % equiv), AgSbF\(_6\) (7.5 mg, 0.02 mmol, 10 mol % equiv) and Cu(OAc)\(_2\) (7.9 mg, 0.04 mmol, 20 mol % equiv) was carefully weighed to a vial equipped with a magnetic stirrer bar and a tightly-screwed cap. Aryl phosphonate (0.22 mmol, 1.0 equiv) in dichloroethane (0.5 mL) was then added, followed by ethyl acrylate (0.44 mmol, 2.0 equiv). The reaction mixture was flushed with oxygen for 30 seconds and stirred at 110 °C for 15 h, and cooled to room temperature. The crude product was concentrated in vacuo and purified by flash column chromatography (ethyl acetate:hexane = 1:1) to afford the desired alkenylated product.
Diethyl o-tolyl phosphonate (64a): $^1$H NMR (400 MHz, CDCl$_3$): δ 7.94-7.88 (m, 1H), 7.44-7.40 (m, 1H), 7.28-7.24 (m, 2H), 4.18-4.05 (m, 4H), 2.57 (s, 3H), 1.32 (t, $J = 7.1$ Hz, 6H); $^{13}$C NMR (400 MHz, CDCl$_3$) δ 155.2, 134.1 (d, $J_{C-P} = 10.5$ Hz), 132.8, 131.5, 131.3, 130.9, 126.8, 125.6, 119.7, 115.1, 62.3, 21.3, 16.4 (d, $J_{C-P} = 6.8$ Hz); $^{31}$P NMR (400 MHz, CDCl$_3$): δ = 20.1288; IR (film) 3053.32, 2304.94, 1712.79, 1421.54, 1361.74, 1265.30, 1222.87, 894.97, 727.16 cm$^{-1}$; HRMS (EI) calcd for C$_{11}$H$_{17}$O$_3$P (M$^+$) 229.0994, found 229.0990.

Diethyl (2-ethylphenyl) phosphonate (64b): $^1$H NMR (400 MHz, CDCl$_3$): δ 7.92-7.86 (m, 1H), 7.49-7.43 (m, 1H), 7.34-7.21 (m, 2H), 4.21-4.04 (m, 4H), 2.97 (q, $J = 7.8$ Hz, 2H), 1.35-1.23 (m, 9H); $^{13}$C NMR (400 MHz, CDCl$_3$) δ 148.4 (d, $J_{C-P} = 10.5$ Hz), 134.0, 132.8, 129.8 (d, $J_{C-P} = 15.3$ Hz), 125.5 (d, $J_{C-P} = 15.3$ Hz), 62.1 (d, $J_{C-P} = 5.7$ Hz), 27.3, 16.5 (d, $J_{C-P} = 5.7$ Hz), 15.8; $^{31}$P NMR (400 MHz, CDCl$_3$): δ = 20.3413; IR (film) 2983.88, 1712.79, 1595.13, 1568.13, 1475.54, 1392.61, 1361.74, 1265.30, 1222.87, 894.97, 727.16 cm$^{-1}$; HRMS (EI) calcd for C$_{12}$H$_{19}$O$_3$P (M$^+$) 243.1150, found 243.1151.

Diethyl (2-chlorophenyl) phosphonate (64c): $^1$H NMR (400 MHz, CDCl$_3$): δ 8.03-7.97 (m, 1H), 7.50-7.31 (m, 3H), 4.24-4.08 (m, 4H), 1.21-1.29 (m, 6H); $^{13}$C NMR (400 MHz, CDCl$_3$) δ 136.9, 136.0 (d, $J_{C-P} = 7.6$ Hz), 133.7, 130.9 (d, $J_{C-P} = 10.5$ Hz), 128.3, 126.5 (d,
$J_{C-P} = 13.4$ Hz), 62.7 (d, $J_{C-P} = 5.7$ Hz), 16.4 (d, $J_{C-P} = 6.7$ Hz); $^{31}$P NMR (400 MHz, CDCl$_3$): $\delta = 15.1435$; IR (film) 2983.88, 1712.79, 1583.56, 1566.20, 1456.26, 1392.61, 1367.53, 1163.08, 1060.85, 758.02 cm$^{-1}$; HRMS (EI) calcd for C$_{10}$H$_{14}$O$_3$PCl(M$^+$) 249.0447, found 249.0441.

Diethyl [1,1'-biphenyl]-2-yl phosphonate (64d): $^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 8.07-8.01 (m, 1H), 7.57-7.26 (m, 8H), 3.96-3.80 (m, 4H), 1.11 (t, $J = 7.1$ Hz, 6H); $^{13}$C NMR (400 MHz, CDCl$_3$) $\delta$ 146.3 (d, $J_{C-P} = 9.6$ Hz), 141.6, 134.0 (d, $J_{C-P} = 9.6$ Hz), 132.1, 131.5 (d, $J_{C-P} = 14.4$ Hz), 129.5 (d, $J_{C-P} = 10.5$ Hz), 127.9, 127.6, 127.5, 127.4, 127.1, 126.9, 126.1, 62.0 (d, $J_{C-P} = 5.7$ Hz), 16.2 (d, $J_{C-P} = 6.7$ Hz); $^{31}$P NMR (400 MHz, CDCl$_3$): $\delta = 18.7995$; IR (film) 3016.67, 2399.45, 1712.79, 1591.27, 1562.34, 1469.76, 1444.68, 1392.61, 1367.53, 1217.08, 1139.93, 1095.57, 1028.06, 974.05 cm$^{-1}$; HRMS (EI) calcd for C$_{16}$H$_{19}$O$_3$P(M$^+$) 291.1150, found 291.1148.

Diethyl (4-methoxy-2-methylphenyl) phosphonate (64e): $^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 7.88-7.85 (m, 1H), 6.78-6.75 (m, 2H), 4.13-4.06 (m, 4H), 2.53 (s, 3H), 1.33-1.30 (m, 6H); $^{13}$C NMR (400 MHz, CDCl$_3$) $\delta$ 163.4, 144.2, 136.4 (d, $J_{C-P} = 12.4$ Hz), 132.2, 128.6, 117.3 (d, $J_{C-P} = 15.3$ Hz), 61.9 (d, $J_{C-P} = 4.8$ Hz), 55.4, 21.5, 16.4 (d, $J_{C-P} = 6.7$ Hz); $^{31}$P NMR (400 MHz, CDCl$_3$): $\delta = 21.0401$; IR (film) 3412.08, 2985.81, 1699.29, 1637.56, 1591.27, 1363.67, 1166.93, 1109.07, 1022.27, 530.42 cm$^{-1}$; HRMS (EI) calcd for C$_{12}$H$_{19}$O$_4$P(M$^+$) 259.1099, found 259.1097.
